ESM 1. Supplement to Section 1: Differences between this paper and Camuffo 1984, 2002

A reader might wonder why another paper after Camuffo 1984, 2002.

In Camuffo 1984, the observations and their metadata were crudely summarized in 2 1/3 pages; in the 2020 paper, everything has been carefully investigated and documented with original archive documents and photographs.

In Camuffo 1984, there were no pictures, drawings or diagrams representing instruments, exposure and locations; in the 2020 paper, all of them have been clearly reconstructed and shown.

In Camuffo 1984, not all rain gauge types and exposures were known; in the 2020 paper, the most likely instrument shapes and exposures are presented.

In Camuffo 1984, the gap 1764-67 was not solved and the solution proposed by Toaldo was recognized to be unacceptable; in the 2020 paper, two solutions are proposed: i) the parallel series taken in Venice by Temanza and Pollaroli, and ii) the use of indexes analyzing and calibrating the contemporary Morgagni Log.

In Camuffo 1984, the Bologna precipitation series had not been recovered yet and could not be used as a reference and potentially to fill gaps; in the 2020 paper, the Bologna series has been largely used to check and validate the Padua series, and to distinguish the climate signal from instrumental bias.

In Camuffo 1984, according to the literature, it was believed that the raingauge in the Specola was always kept in the same position; in the 2020 paper, it has been demonstrated that it was relocated a number of times. In addition, in this work, the different response of a raingauge located on the roof or at ground level has been assessed.

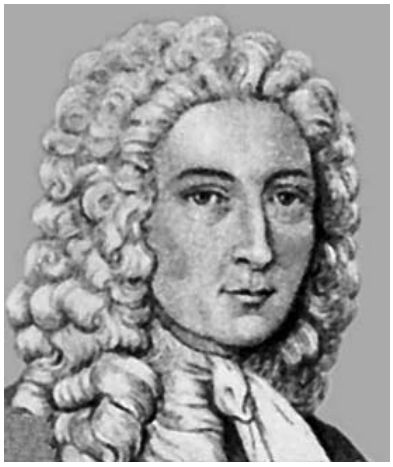
In Camuffo 1984, according to the literature, it was believed that readings were regularly taken; in the 2020 paper, it has been demonstrated that readings from 1811 to 1861 were taken irregularly, in the day (or days) after the precipitation, shifting readings to the next day(s), or recording a depth cumulated in the previous two or three days.

These and other differences are essential to interpret and/or correct data. They have been highlighted in the Introduction of the 2020 paper and many of them are going to be put in practice in the paper in progress, devoted to the correction and analysis of the precipitation series.

Camuffo 2002 deals with temperature records, not with precipitation. The rain gauge is different from a thermometer and its exposure too, especially when Poleni took temperature readings indoors (1725-1764). Only the readers and the building are the same. However, it was recently discovered that the bad health of an observer was determinant to introduce delayed

precipitation readings, affecting the regularity and frequency of observations. This minimalist observing style continued for some 50 years but was not mentioned in the previous papers. This fact did not cause particular consequences on the temperature and pressure readings that were taken without getting wet in the case of rain, but had tremendous consequences on the precipitation frequency and less in its amount, and determined the need of revising the previous work (Camuffo 1984).

ESM 2. Supplement to Section 1: Key Observers



Marquis Giovanni Poleni (1683-1761)
He was a leading scientist in various disciplines, close friend of Giovan Battista Morgagni, Jacopo Bartolomeo Beccari, Eustachio Manfredi and other scientists of the Bologna University.
In 1709, he started to build meteorological instruments (assisted by his friend Giovan Battista Morgagni) and to make meteorological observations. Other key topics were hydrology and river flows, architecture and statics, especially concerning the dome of St. Peter, Rome.
He was appointed Professor at the Padua University and had various chairs in: Astronomy and Meteors (1710); Physics (1715); Mathematics (1719); Physics and experimental philosophy (1739); Navigation sciences and constructions (1755).

In 1710, Isaac Newton appointed him fellow of the Royal Society, London. Other fellowships: Society of Sciences of the Elector of Brandenburg, Berlin (1715); Institute and Academy of Sciences and Arts, Bologna (1723); St. Petersburg Academy of Sciences, St. Petersburg (1735); Académie Royale des Sciences, Paris (1739).

In 1724, he adhered to the meteorological network of the Royal Society, London.

In 1734, he won a prize of the Académie Royale, Paris, for a pressure anemometer.

In the last period of his life, he was assisted by his son Francesco, who continued the meteorological readings for four years after Giovanni died.

Giovan Battista Morgagni (1682-1771)
He was internationally recognized, and considered the father of the modern pathological anatomy conceived as an exact science. He graduated in 1701 in philosophy and medicine at the University of Bologna. He was appointed to the chair of Theoretical medicine in 1711, and Anatomy in 1715 at the Padua University. His most famous publication was *De sedibus et causis morborum per anatomen indagatis* (The Seats and Causes of Diseases investigated by Anatomy, Printed by Giuseppe Remondino, Padua, 1765). He was Fellows of *Sacri Romani Imperii Academia Caesarea Leopoldino-Carolina Naturae Curiosorum,* Halle, Saxony (1708); Royal Society, London (1724); Académie Royale des Sciences, Paris (1731); St. Petersburg Academy of Sciences, St. Petersburg (1735); Royal Academy of Sciences, Berlin (1754). He was a close friend of Poleni.
In 1709, in Venice, Morgagni helped Poleni in the construction of thermometers and barometers, and in 1740 he started a parallel series of weather observations in Padua.

ESM 3. The Directors of the Specola

The Specola was founded in 1767 and it was part of the University until 1923; it was the seat for teaching, and performing astronomical and meteorological observations. The first two Directors were interested in both disciplines and had the chair of Astronomy and Meteorology. Later, this chair was dismissed and the new Directors were interested only in astronomy, had a chair of Astronomy, and charged an assistant to perform meteorological observations. However, the Director was responsible for any decision, even if he was not always expert of meteorology. The Chair of Astronomy was linked to the direction and this assignment was a lifetime job (but this simple rule, however, had some exceptions, as explained later).

The Directors of the early period deserve further attention for their relevance. It should be noted that some reference dates are differently reported in authoritative sources, as the period of real activity might be different from the receipt of the official assignment (for more details see the bibliography). The most important details of the Directors in the period in which the Specola exerted meteorological activity are reported in Table ESM.1.

Giuseppe Toaldo (1741-1797). He was the founder of the Specola and a supporter of the observational activity both in astronomy and meteorology. He was a leading scientist and reached international renown thanks to his studied about the connections between lunar cycles, meteorology, agriculture and health.

In 1762, the chair of Astronomy and Meteors held by Gian Alberto Colombo became free and the Senate approved that Toaldo had it; however, the decree was formally approved only in 1764 and the chair was renamed 'Astronomy and Meteorology with elements of Geography'. Then, Toaldo was commissioned to choose the best location for the Astronomical Observatory whose construction had been deliberated by the Venetian Senate in 1761. He also supervised the building work, which started in 1767 and lasted 10 years, transforming the main tower of the mediaeval Castle of Padua into the Specola.

Appreſſo Gio: Manfrè.
CON LICENZA DE' SUPERIORI.

The results of his researches on the influence of climate on heath and agriculture are presented in his most famous publication: *Della vera influenza degli astri, delle stagioni e mutazioni di tempo. Saggio meteorologico* (On the true influence of celestial bodies, seasons and weather changes – A meteorological essay) (1770). In 1773, Toaldo founded the *Giornale Astro Meteorologico* (Journal concerning Astronomy and Meteorology). The journal included astronomical ephemerides, weather statistics, a description of the climatic features of the previous year, and hosted articles and climate data taken by a network of observers. It started in 1773 and was continued until 1848 by the subsequent Directors of the Astronomical Observatory. With this journal, Toaldo extended the network of weather observers. In 1777, the Specola and adjacent building (the Astronomer House) were ready and all weather instruments were located in their final position.

In 1782, Toaldo adhered to the network of the *Societas Meteorologica Palatina*, Mannheim. He died in 1797, just after the occupation of the French Army and the fall of the Venice Republic. Three months before his death, he wrote an article to explain the relationships between the local traditional units and the modern ones, imposed by the French Army, e.g. measuring time from midnight instead of twilight (i.e. following the tradition of Rome based on the guard duty in the army, and the middle age use related to the sound of the Church bells for prayers) with conversion tables over the calendar year.

Table ESM1. Directors of the Specola when the meteorological observations were performed

Portrait	Name	Life span	Director	Scientific interest
	Giuseppe Toaldo	1741-1797	1767-1797	Astronomy & Meteorology
	Note: He refurbished a mediaeval tower to transform it in a Specola with advanced instruments; he enhanced meteorology and linked it to astronomy and health at international level; he studied climate cycles; he adhered to the *Societas Meteorologica Palatina*, Mannheim and founded the *Giornale Astro-Meteorologico*.			
	Vincenzo Chiminello	1741-1815	1797-1811 (1811 actually; 1815 officially)	Astronomy & Meteorology
	Note: He carried on the Toaldo's legacy (including the *Giornale Astro-Meteorologico*) and developed new meteorological instruments.			
	Francesco Bertirossi-Busata	1778-1825	He was not Director but observed in the 1815-1817 gap	Astronomy
	Note: He took weather observations and directed the *Giornale Astro-Meteorologico*. Although in poor health, he observed till the last two months of life.			
	Giovanni Santini	1787 -1877	1817-1877	Astronomy
	Note: He was not particularly interested in meteorology. He did not support the weather observations with auxiliary personnel during the Bertirossi-Busata illness. He ordered to use the big dome of the Meridian Circle Room to collect rain. Observers: Bertirossi-Busata (1817-25); Carlo Conti (1827-42); Gaetano Pietropoli (1834–1847); Virgilio Trettenero (1848–1863); Jacopo Michez (1861–1866); Enrico Nestore Legnazzi (1855–1862); Lorenzoni (1864-67); Antonio Abetti and Lorenzoni (1868-1879); Ciro Chistoni (1874). The lowest observation quality was with Carlo Conti (1827-42). Thanks to Santini, the Meteorological Logs of Poleni, Morgagni, Beccari and other Toaldo's Correspondents were acquired by the Astronomical Observatory and are now preserved in the Historical Archive.			
	Giuseppe Lorenzoni	1843-1914	1877-1913	Astronomy & Meteorology
	Note: He restored the good meteorological practices. Observers: Francesco Miari-Fulcis (1877 and 1881-1886); Giuseppe Naccari (1879–1880), Giuseppe Ciscato (1886–1894); Antonio Maria Antoniazzi (1894–1999); Roberto Sabena (1899–1902); Giuseppe Alessandro Favero (1902–1911).			
	Antonio Maria Antoniazzi	1872-1925	1913–1925	Astronomy
	Note: He worked in a very difficult time (during and at the end of the World War I), essentially without staff, and he could not be interested in meteorology. During WWI, the Italian Army established the 1915-1918 weather forecast office in the Specola, and the activities were made and controlled by military personnel. Before and after, for routine observations, he relied on the technician Sante Mioni (1874-1928).			
	Giovanni Silva	1882-1957	1926-1952	Astronomy
	Note: He was not interested in meteorology. He developed a new Astronomical Observatory in Asiago, on the Alps, and in 1938 closed any meteorological activity in the Specola that was mainly used for teaching Astronomy. The technicians continued readings till 1959, writing on notepad sheets.			

Vincenzo Chiminello (1741-1815). He was a very accurate meteorologist and astronomer, nephew and co-worker of Toaldo. In 1779, he was appointed assistant astronomer. He discovered the influence of the astronomical forces in determining daily barometric pressure cycle, similar to the tidal cycle. In 1783, he won the prize for a tender launched by the Theodoro-Palatina Academy of Sciences, Mannheim, for the most accurate hygrometer. Chiminello proposed a goose pen fixed to a glass tube and filled with mercury, with a complex system to correct readings for temperature.

In 1797, after Toaldo's death, the University informally appointed him to the chair of Astronomy, Meteors and Geography, that was connected with the responsibility of Director of Specola. However, this was a bad period: the Venice Republic fall, and the Napoleon's troops arrived in the north-east of Italy; the treaty of Campo Formio (17 October 1797) partitioned the Veneto region between France and Austria and Padua suffered a long period of political and administrative confusion. Only in 1806, when Austria had finally organized a local government, Chiminello received the official assignment of Astronomy as well as of Director of the Faculty of Physics and Mathematics.

Chiminello was not a healthy man. In 1809, he had a first apoplectic fit, but continued his activity. He taught until 1811, and then he had a second, stronger, apoplectic fit, so forcedly abandoned the Specola. Some sources consider this year the last one of his activity. He was removed from the charge of teaching, but he kept the title of Director, compensating him for the years without salary that followed the Napoleon invasion, from 1797 to 1806. The teaching problem was solved with an informal assignment, in 1812, to Giovanni Santini, who was also the informal Director during the Chiminello's illness. Chiminello died for a third fit in 1815. Officially, the Specola remained widow of Director until 1817.

Francesco Bertirossi-Busata (1778-1825) was never Director of the Specola, but had to bridge a difficult period between the apoplectic fit of Chiminello and the appointment of the new Director, Giovanni Santini. A note is due to explain the lower quality of the series during his period. Bertirossi-Busata studied Philosophy and Mathematics with Chiminello and took his degree in 1807. Then he started to work at the Specola, in 1813 he was appointed astronomer and in 1817 astronomer for calculations. He cared celestial mechanics and star aberration, but he was also charged for weather observations. In 1809, during the first illness leave of Chiminello, he cared the publication of the *Giornale Astro-Meteorologico* founded by Toaldo and became Director of this journal in 1819. However, from 1816 Bertirossi-Busata was affected by gallbladder and liver sickness and could not take regular weather observations. He operated always without assistants, so observations are missing in the last two months of his life, September and October 1825. This was a bad political period under the occupation of Austria, and the Specola personnel had to work with very limited resources and low salary.

Giovanni Santini (1787-1877). He was a good and a famous astronomer, less interested in meteorology. In 1806, he was appointed assistant astronomer; in 1812, he was informally appointed to teach Astronomy; in 1817, he was officially appointed Professor of Astronomy and Director of the Specola. He disregarded the problem of the illness of Bertirossi-Busata and did not charge any other personnel to assist him in his most difficult periods, and this created discontinuities and gaps in the series. For short periods, in his long life, Santini interrupted teaching, being substituted by his assistants Virgilio Trettenero and Giuseppe Lorenzoni. He died in 1877, at the age of ninety, keeping the direction of the Observatory until the last day of his life. Concerning the precipitation series, he built the Meridian Circle Room and ordered to use its dome to collect rainfall from 1838 to 1877, creating a non-homogenous gauge. However, the catchment area was so large that the result was good.

Giuseppe Lorenzoni (1843-1914). After Enrico Nestore Legnazzi was cast out for political reasons and Virgilio Trettenero died in 1863, the director Santini appointed Lorenzoni assistant professor of Astronomy and put him in charge of meteorological observations at the Specola. Lorenzoni was a last year student and got a degree in engineering in 1864. In that period – the last years of Austrian domination in Veneto – the Observatory was deprived of personnel, except for the assistant astronomer Jacopo Michez which, however, was particularly arrogant and unpopular to both the Director and the other people who lived in the Specola. Even the astronomical and meteorological observations suffered for the bad personality of Michez in these years.

In 1867, after the annexation of Veneto to the Kingdom of Italy, Lorenzoni had the regular assignment of the astronomy lessons, obtaining the appointment as extraordinary professor in 1872; in 1878, after the death of Santini, he became full professor and director of the Observatory, a position he held until 1913. His scientific activity ranged from classical astronomy to spectroscopy, up to geodesy, but he was interested also in the good meteorological practice, especially in the first period of his direction. From 1878, in fact, he rearranged the meteorological observations and the related instrumentation under the guidance of Pietro Tacchini, director of the Central Meteorology Office and his close friend.

Lorenzoni devoted himself to teaching: under his guidance the Padua astronomy school grew up and formed leading astronomers, like Antonio and Giorgio Abetti - father and son - both directors of the Arcetri Astrophysical Observatory, Emilio Bianchi, director of the Brera Observatory and Giuseppe Ciscato, director of the Carloforte station.

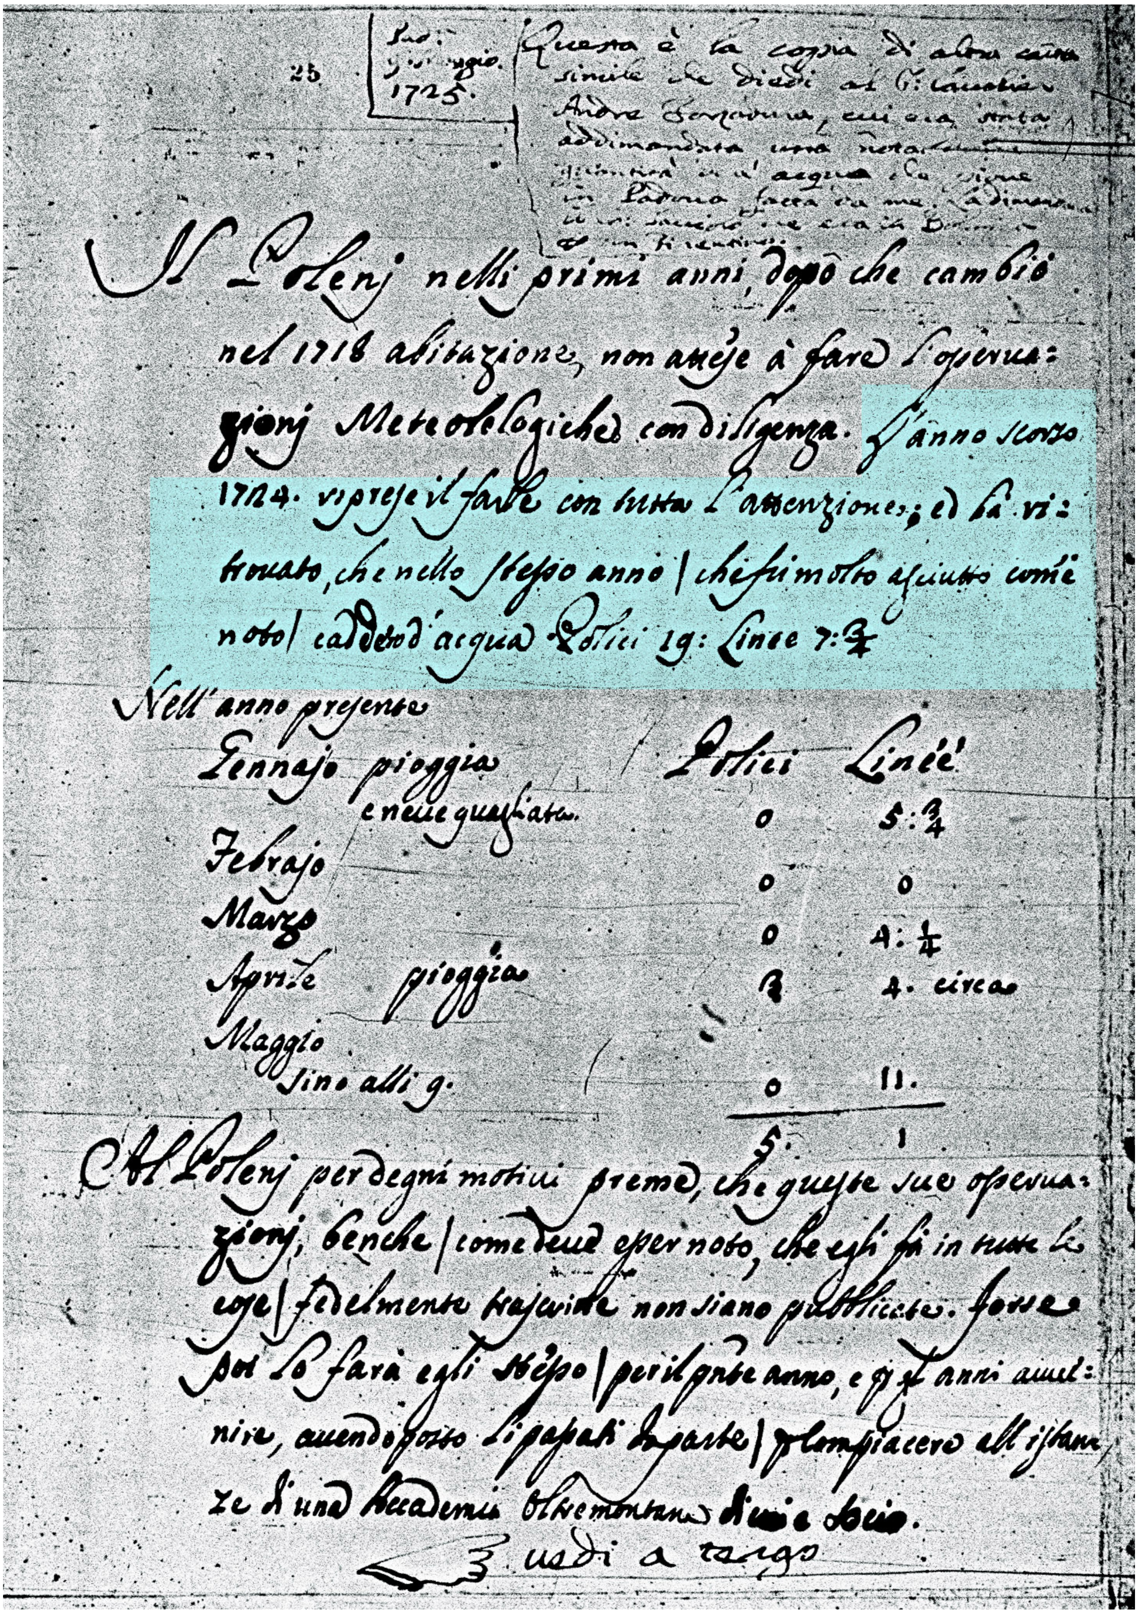
ESM 5. Supplement to Section 2: Examples of the original documents



25
Pad: 9 maggio 1725.
Questa è la copia di altra carta simile che diedi al Sig. Cavalier Andrea Forzadura, cui era stata addimandata una nota

Il Sig. Poleni nelli primi anni, dopo che cambiò nel 1718 abitazione, non ameje à fare l'osservazioni Meteorologiche con diligenza. L'anno scorso 1724. vi prese il farle con tutta l'attenzione; ed ha ritrovato, che nello stesso anno (che fu molto asciutto come noto) caddero d'acqua Pollici 19: Linee 7:¾

Nell'anno presente

	Pollici	Linee
Gennajo pioggia e neve liquefatta	0	5:¾
Febrajo	0	0
Marzo	0	4:¼
Aprile pioggia	3	4. circa
Maggio sino alli 9.	0	11.
	5.	1

Il Sig. Poleni per degni motivi preme, che queste sue osservazioni, benche (come deve esser noto, che egli fa in tutte le cose) fedelmente trascritte non siano pubblicate. Forse poi lo farà egli stesso (per il presente anno, e per gl' anni avvenire, avendo posto li passati da parte) per compiacere all'istanze d'una Accademia Oltremontana di cui è socio.

usadi a tergo

Fig.ESM1a Front page of the letter to Cavalier Forzadura. The cyan highlighted text specifies: "Past year, 1724, (Poleni) continued very carefully his measurements, and he found that in that year, that was very dry as known, the precipitated amount was 19 inch, 7 ¾ lines". The letter also reports the monthly totals from January to May 9th,1725. (© Marciana Library, Venice, Poleni unpublished manuscripts, Mss. It., CL. IV, N.631, Coll. 5354, folio (sheet) 25 front)

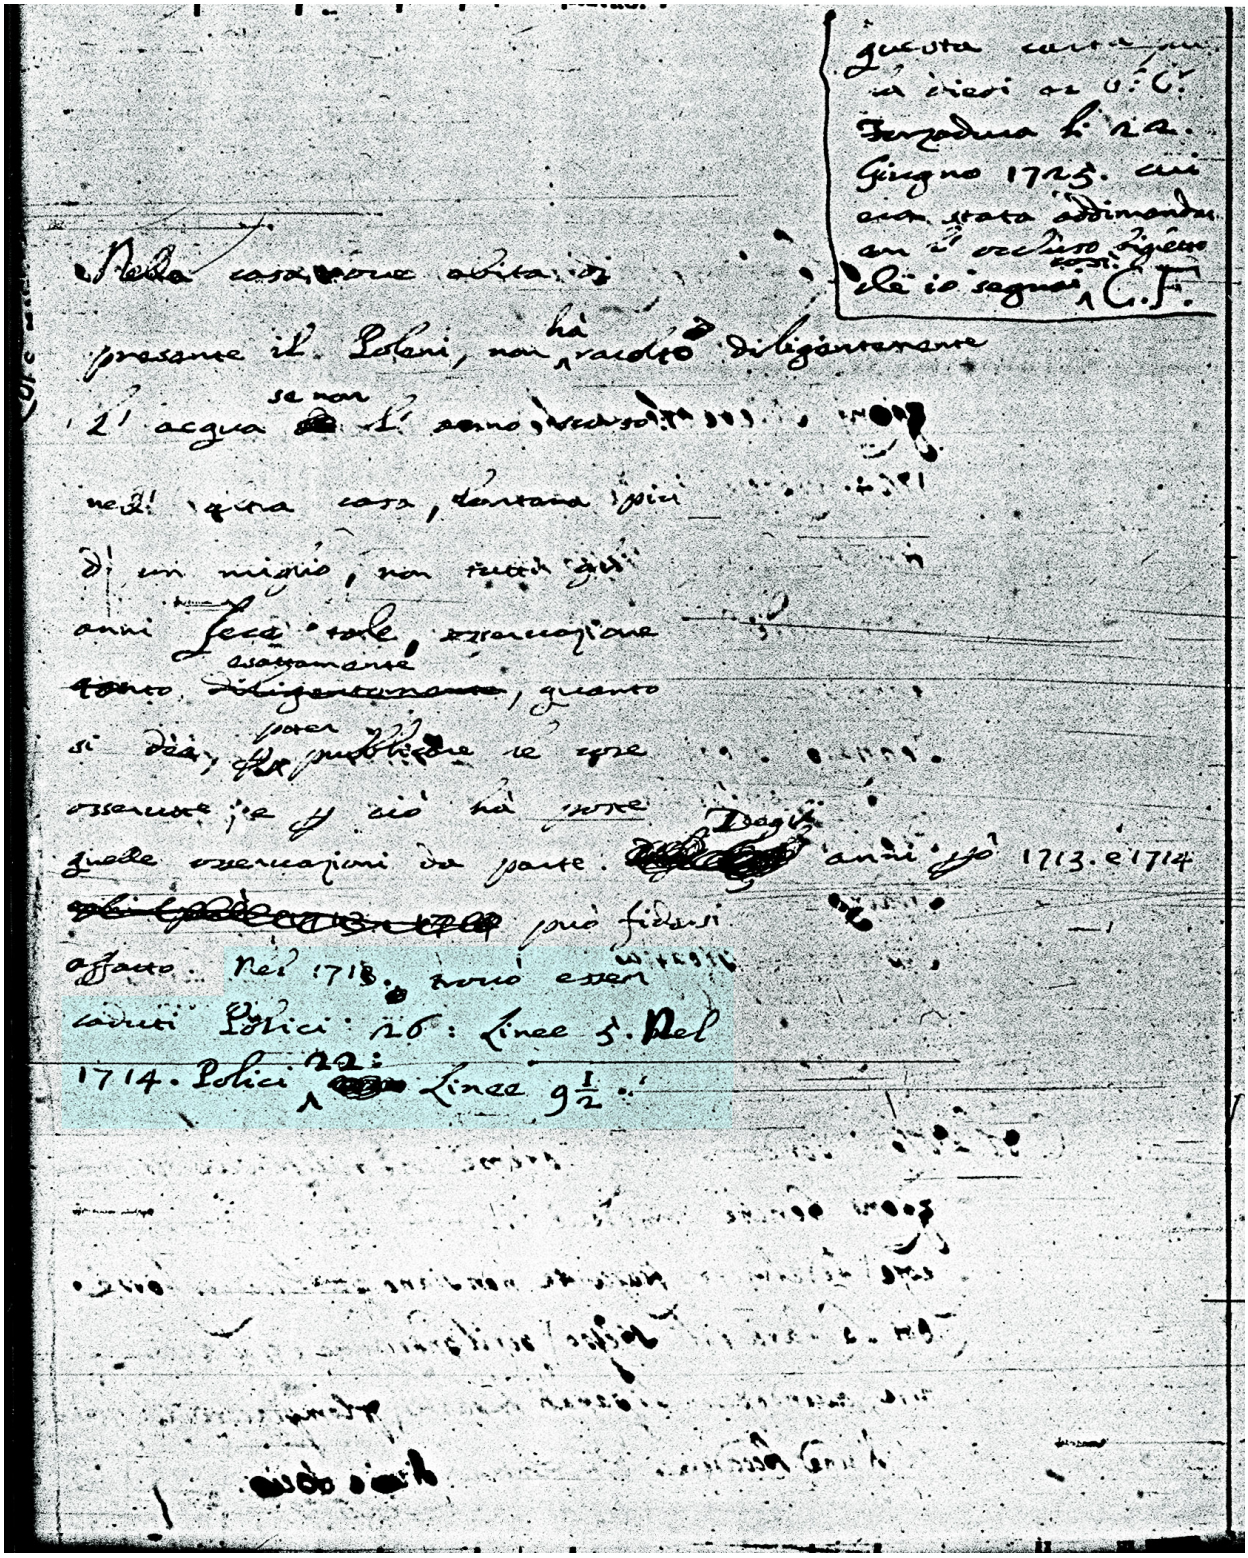


Fig.ESM1b Back page of the letter to Cavalier Forzadura. The cyan highlighted text specifies: “In 1713, (Poleni) found a precipitated amount of 26 inch, 5 lines. In 1714, 22 inch 9 1/2 lines”. ESM 6. Supplement to Section 2: The Poleni house

From 1724 to 1761 Giovanni Poleni, and to 1764 his son Francesco Poleni, lived in S. Giacomo District n. 3959, today Beato Pellegrino Street, n. 5, in the northern side of Padua. The Map of Padua by Giovanni Valle (1781), with size 180 cm by 202 cm, scale 1:2144, reports an accurate description of the city, with buildings, rivers and canals (Fig.ESM3a). The aerial view in Fig.ESM3b shows the Poleni house and the garden today, with the Bovetta Canal earthed, while Fig.ESM3c shows the Bovetta Canal as it was in the XVIII century.

The building was a refurbished water mill and for this reason is located close to the canal. At the end of the garden, there was a pond with fish, fed by the canal. When the river and the canals were in flood, the garden and some ground floor rooms were flooded. The vertical legend written in the garden of the Map means “School of Chemistry” because, when Giovanni died, Francesco sold the building to Marco Carburi, Professor of Chemistry at the Padua University, for the reason that the building was organized for University lessons, with rooms for lessons and laboratory.

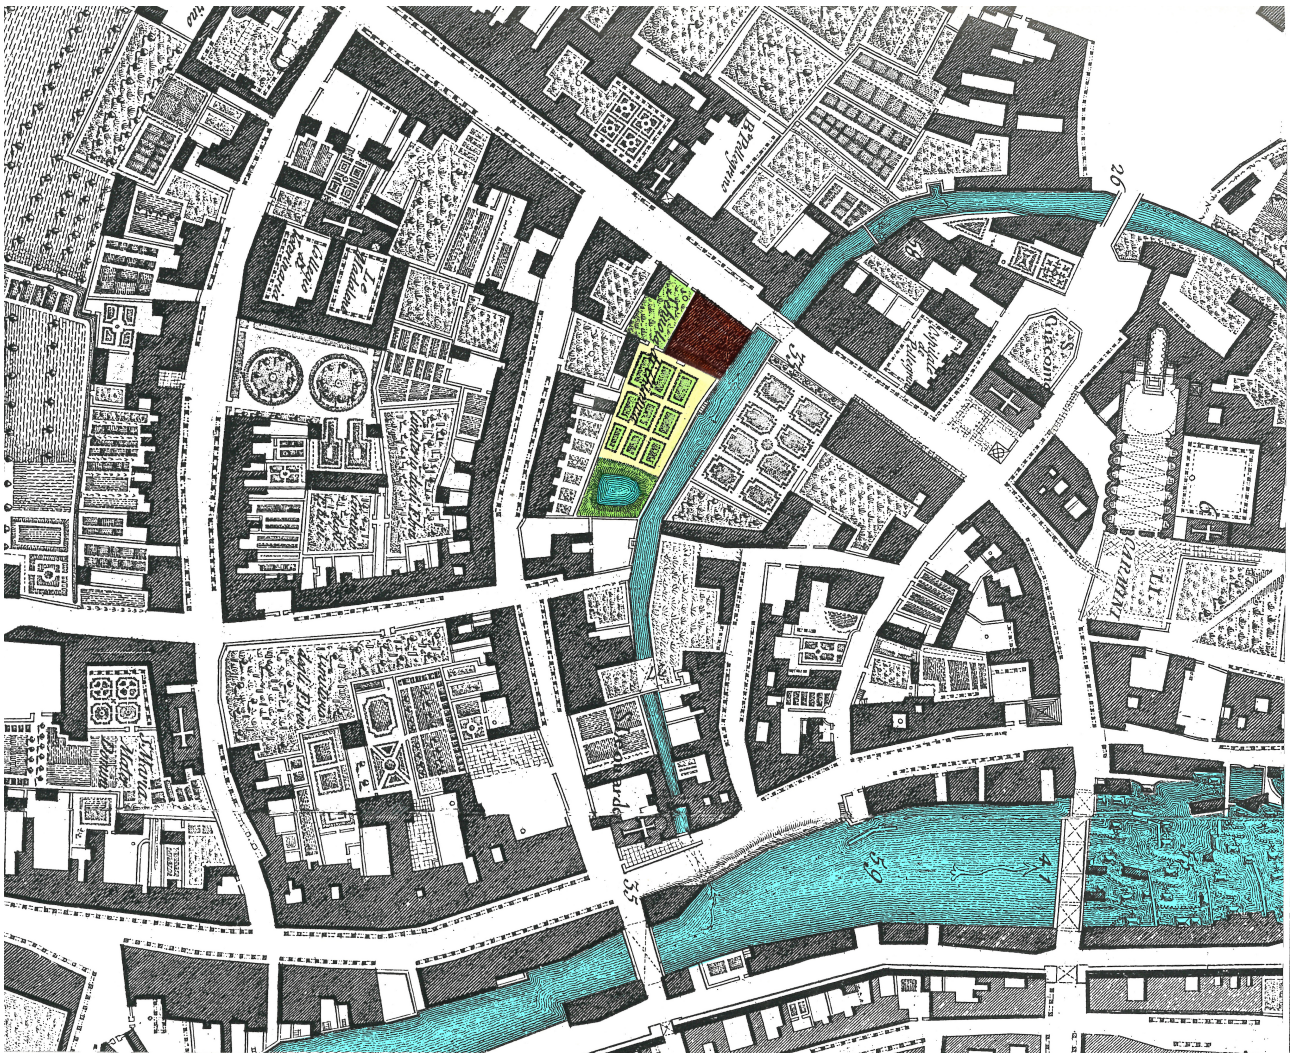

Fig.ESM3 (a) Detail of Map of Padua drawn by Valle (1781) showing the Poleni house (red roof) with (coloured) garden and pond, located on the side of the Bovetta Canal (cyan) flowing on the right side of the building. On the bottom, a branch of the Bacchiglione River with water mills on the right.

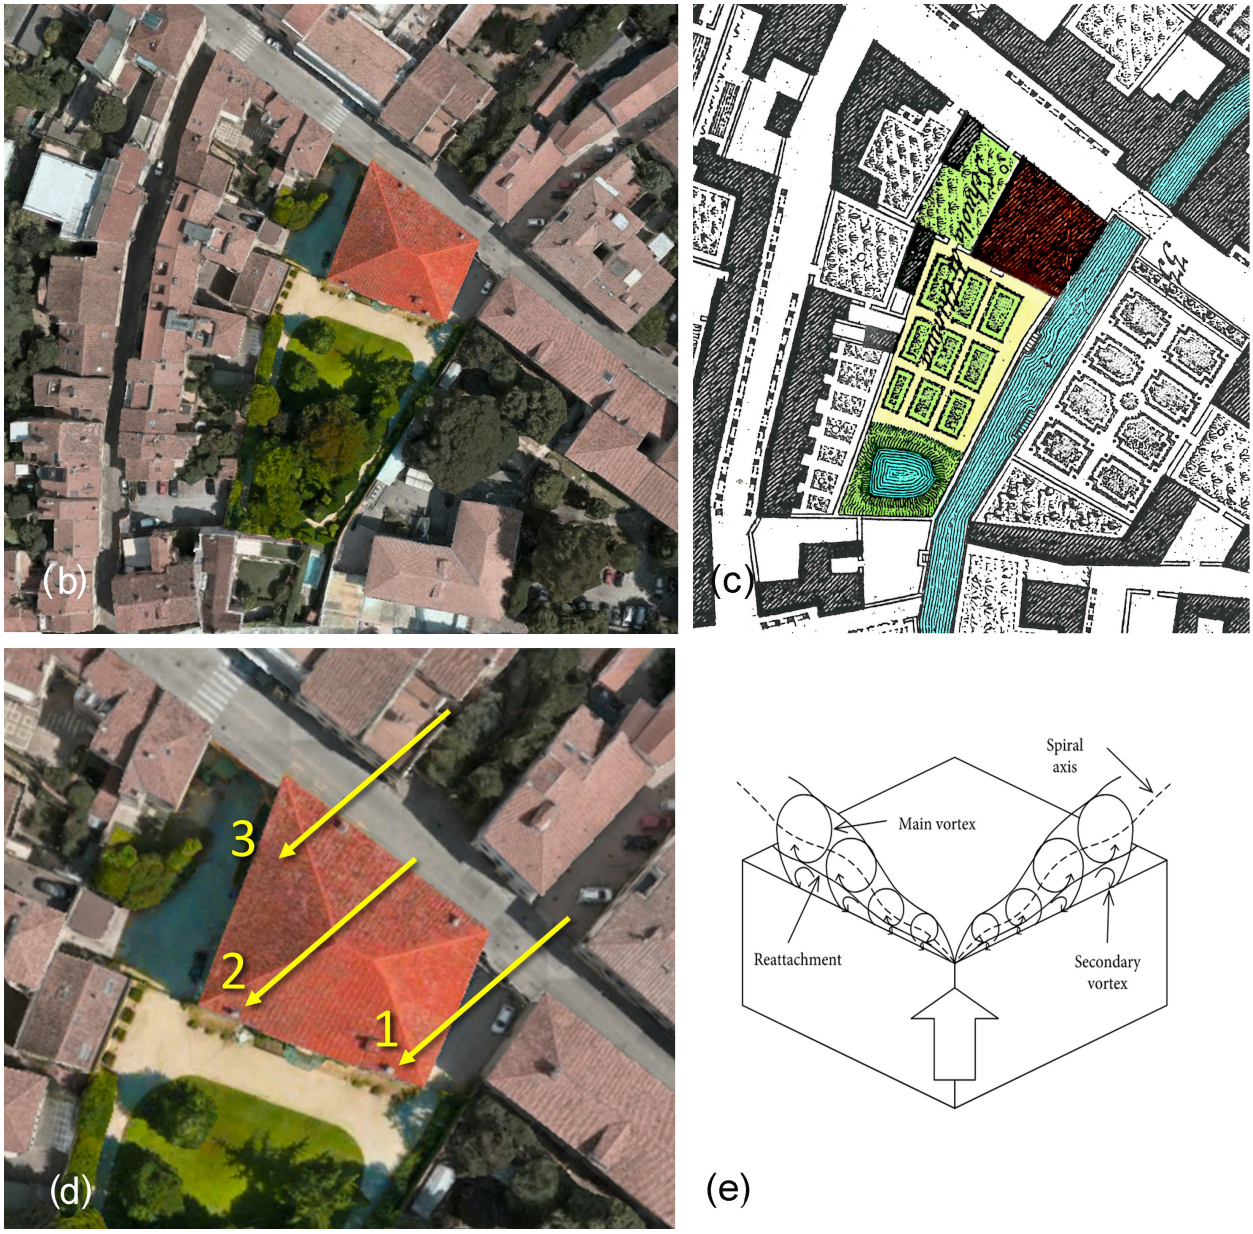

Fig.ESM3 (b) Aerial view of the Poleni house and the garden (from Google Earth). The estate is highlighted with more saturated colours. (c) The same, as it was in the XVIII century with the Bovetta Canal (cyan) flowing on the right side, and a pot (cyan) at the end of the garden (from the Map of Padua drawn by Valle (1781)). (d) Trajectory of windborne raindrops to reach the three chimneys of the Poleni house. Numbers indicating the most likely chimneys: 1 above the library room where he took the temperature and barometric readings; 2 above the laboratory of physics; 3 above the kitchen (now removed from the roof). Poleni had not rooms facing the street and chimneys there should be excluded. Wind turbulence was triggered by the side edge of the roof facing south-east for chimney 1, or facing north-east (i.e. the street side) for chimneys 2 and 3. (e) Example of conical vortices generated on a flat roof edge for an oblique wind direction, and growing with the distance from the edge (from Qiu et al., 2019, CC-BY-4.0).

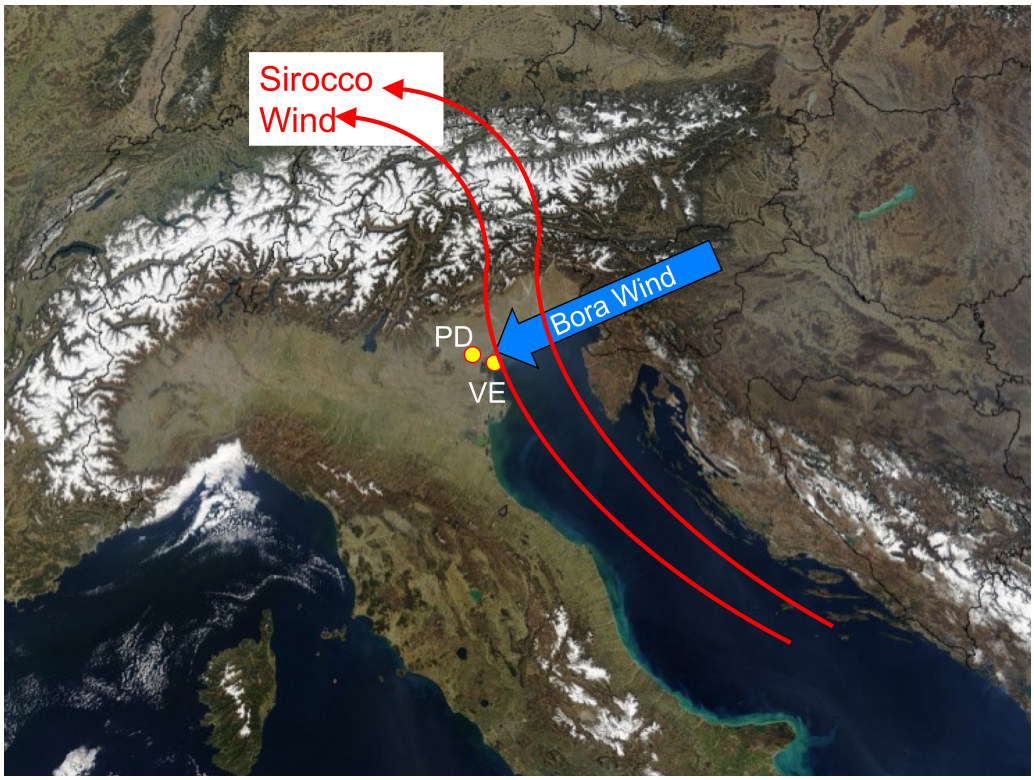
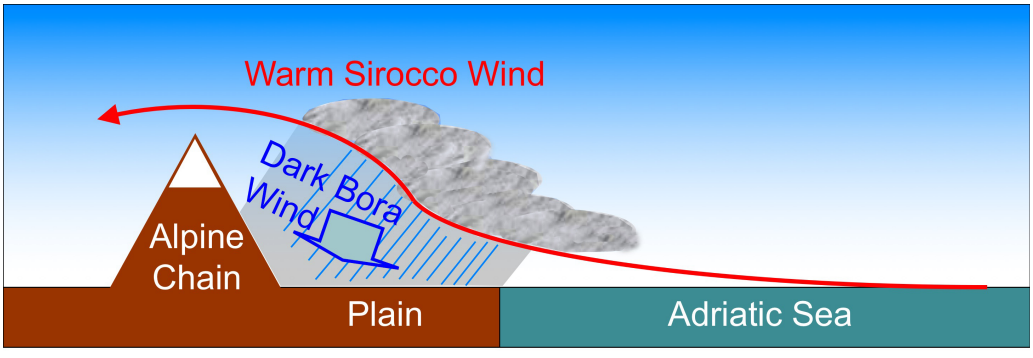
ESM 7. Supplement to Section 2: The Direction of Windborne Rain in Padua

In Venice and Padua, for their geographical position between the Adriatic Sea shore and the Alpine Chain, and the dynamic behaviour of the Sirocco Wind field when crossing the Alps, a wind layering is formed, with the warm and humid Sirocco Wind aloft, and a Bora-type Wind below, blowing from north-east, as shown in Fig.ESM4ab. (Camuffo 1981, 1982, 1990; Camuffo et al. 1979, 1984, 1988).



(a)



(b)

Fig.ESM4 (a) Satellite view of Northern Italy showing the Sirocco Wind flowing above the Alps and generating a Dark Bora with precipitation in Padua (PD) and Venice (VE). (b) Schematic diagram in a SE-NW vertical cross section.

This local wind is meteorologically known as *Dark Bora.* The first part of the name, *Dark,* is due to the thick cloud cover and precipitation that forms at the contact layer between the warm and humid Sirocco and the cold wind below; this thick cover reduces daylight. The second part of the

name, *Bora,* because it is strong and has the typical direction of the Bora winds, i.e. from north-east. The *Dark Bora* occurs when the warm and humid Sirocco wind crosses the Alpine Chain, and is explained with the dynamical mechanism that is triggered and the particular pressure field generated along the lee of the Alpine Chain (Reiter 1971, 1975). In Padua, Venice and the hinterland between the Adriatic Sea and the Alpine Chain, this is the most frequent mechanism to generate rain (Fig.ESM4c). Only summer showers and other precipitation generated by local thermo-convective activity is not strictly controlled by these mesoscale interactions and windborne raindrops may occur with other wind directions, e.g. the local breeze.

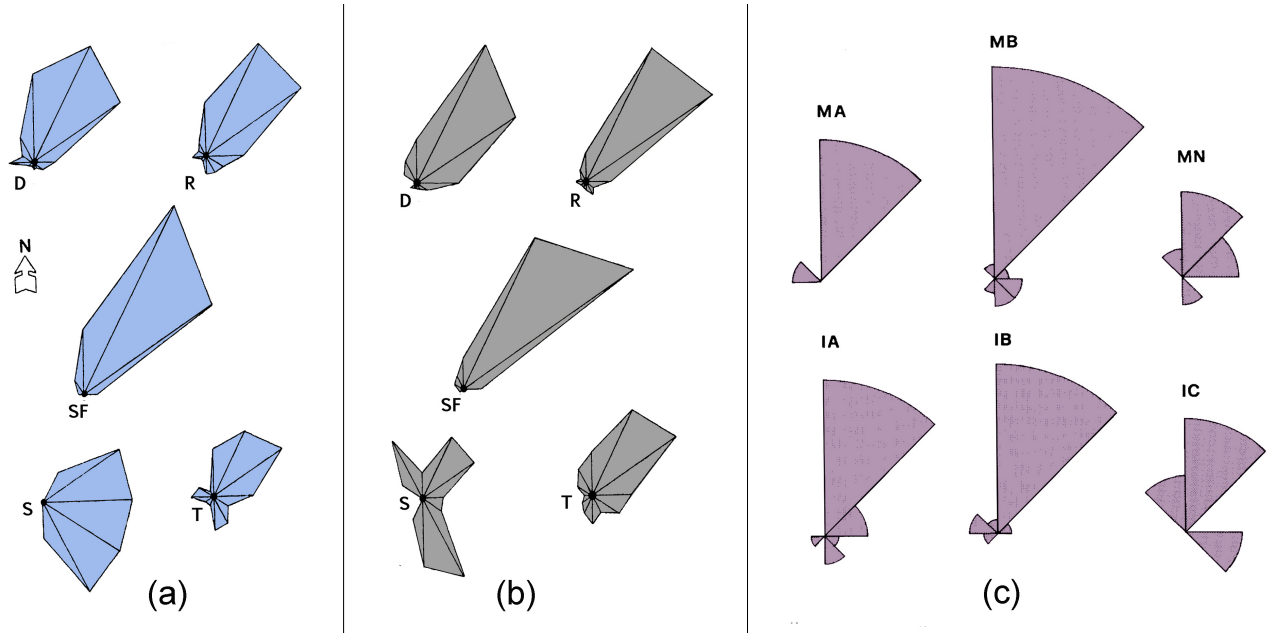


Fig.ESM4c Precipitation roses (direction of windborne drops) in Venice and Padua. (a) Venice S. Nicolò airport, on the sea shore, 1951-61. D drizzle, R rain, SF snow flakes, S showers, T thunderstorm. (b) Venice Tessera airport, on the lagoon shore, 1962-71 (from Camuffo et al. 1984, by courtesy of Elsevier, Science of the Total Environment, ON 4758681017399). (c) Precipitation roses in Padua for different weather types (from Camuffo et al. 1988, by courtesy of Elsevier, Science of the Total Environment, ON 4758671238610).

The combination of Fig.ESM4c and Fig.ESM3(d) explains the trajectory of windborne drops to reach the three chimneys of the Poleni house. Chimneys facing the street should be excluded, because Poleni had no access to this building side (Poleni 1731). Very likely, the funnel was located on the top of chimney 1, except for the period 1737-42, when it was moved to another chimney. Chimney 1 was above the library with the meteorological instruments; chimney 2 above the laboratory of physics on the 1st floor; and chimney 3 above the kitchen.

ESM 8. Supplement to Section 2: Examples of the original documents

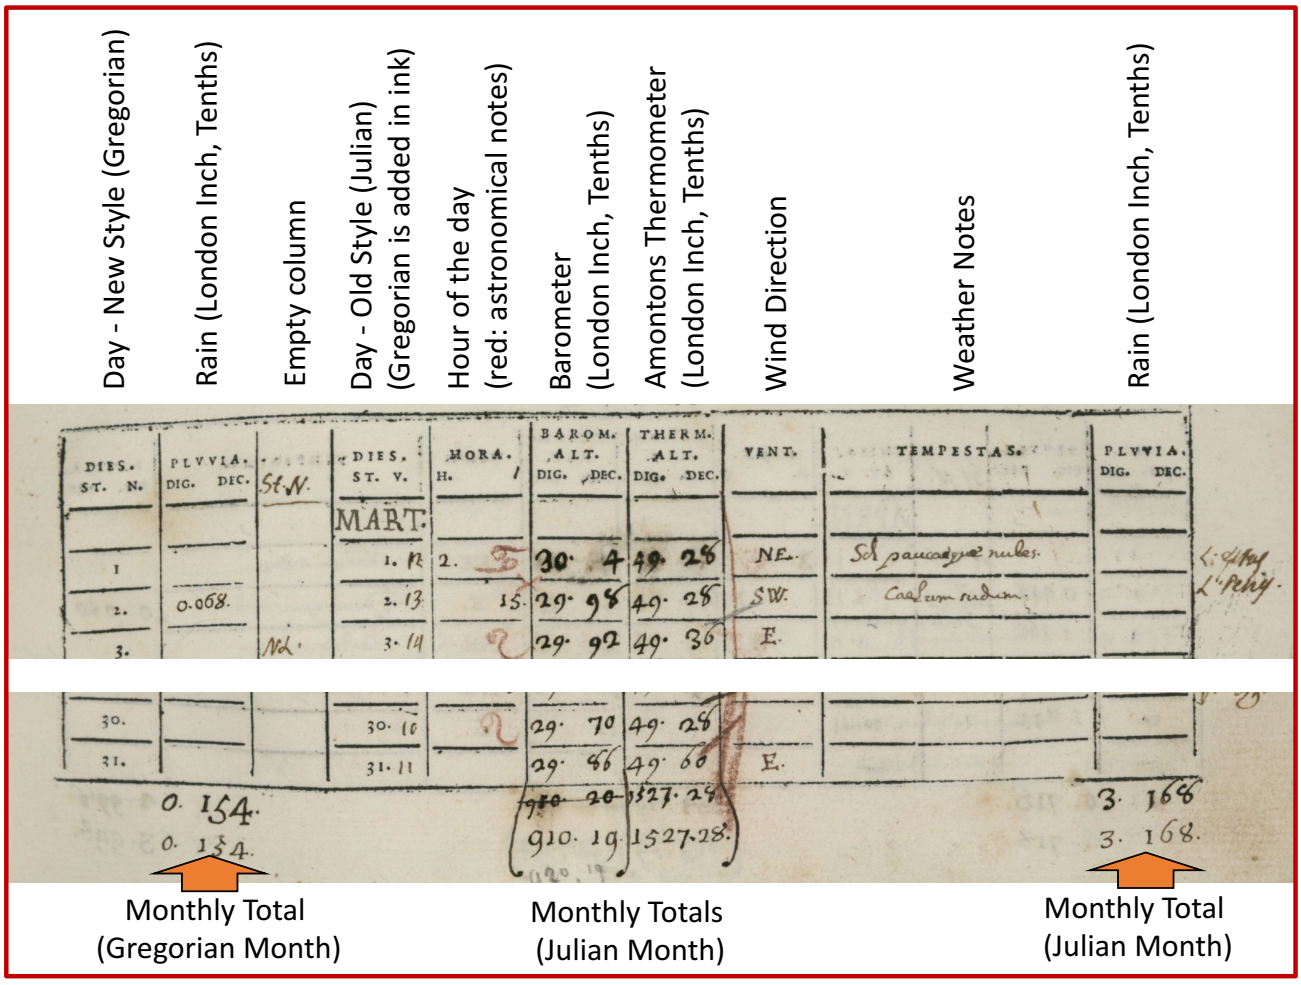

Fig.ESM5a Scheme of Giovanni Poleni Log (top and bottom rows of March 1726). Poleni started on January 1st 1725 Julian Style (JS), i.e. January 12th Gregorian Style (GS). The two columns reporting precipitation are 11 days out of phase, following the two calendar styles, i.e. GS=JS+11d. The monthly totals outside the table, i.e. 0.154 inch and 3.168 inch are different because the Julian and Gregorian months differ between them, i.e. March JS starts on March 12th GS and ends on April 12th GS. The upper monthly totals of precipitation, barometer and thermometer are written by Poleni; the lower ones are a check made by Giuseppe Toaldo. Red pencil notations by Toaldo.

ESM 9. Supplement to Section 2: Raingauge Exposure on the Specola Tower

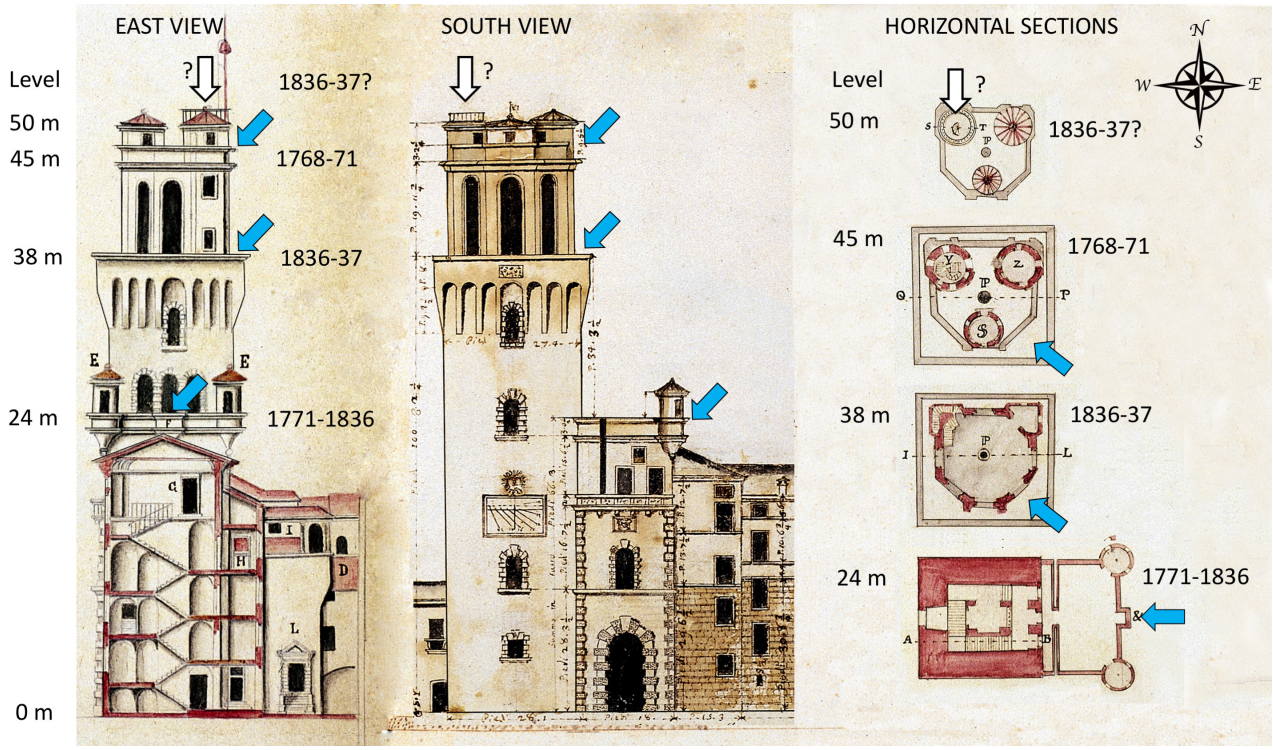

Fig.ESM8 Vertical cross sections of the main Tower (from East and South), and horizontal cross sections of the terraces (on the right) with the most likely locations of the raingauge (cyan arrows with indicated period) from 1768 to 1837. The levels of the locations are reported in correspondence of the exposure years. The likely position in 1836-37 is reported twice: the 38 m level (cyan arrow) is the most probable one, the 50 m level (white arrow, question mark) the less probable. Original sections made by the Architect Domenico Cerato during the refurbishment works in 1768-1771, but rearranged (© Historical Archive of the Astronomical Observatory, Padua, Archivio Antico, Album Cerato).

XVI, fasc. 1).

UFFICIO IDROGRAFICO DEL R. MAGISTRATO ALLE ACQUE

N. 1614

Venezia, 18 ottobre 1910

Risposta alla nota N. .....

del .....

Domani si recherà costì il meccanico di questo Ufficio Monaldi Nicola il quale porterà seco un pluviografo da impiantarsi, come la S.V. crederà più opportuno, in codesto Osservatorio, e ciò in seguito ad autorizzazione data dalla S.V.Illma.

Tutte le spese per tale impianto sono a carico di quest'Ufficio e la somma sarà subito pagata verso la presentazione dei documenti giustificativi necessari.

Con la maggiore osservanza

IL DIRETTORE

G. Magrini

All'Illmo Sig. Direttore
del R.Osservatorio Meteorologico
PADOVA

19 ottobre 1910
Ricevuto oggi l'apparato registratore dalle mani del suddetto meccanico.

Fig.ESM16b Letter of Giovanni Magrini, Director of the Hydrographic Bureau of the Water Magistrate to Lorenzoni, Director of the Meteorological Observatory of the Padua University, with the note that the self-recording siphon raingauge was received on 19 October 2010 (© Historical Archive of the Astronomical Observatory, Padua, Archivio Antico, Atti e dati relativi a strumenti, «Dati relativi ai pluviometri», b. XVI, fasc. 1).

ESM 11. Supplement to Section 3: Homogeneity analysis of the precipitation series

The homogeneity of a climatic series is the prerequisite of every climate study, as non-climatic factors, i.e., changes in observation protocol, observer, instrument, relocation, and so forth, may generate bias that overshadow the real signal. There are two kinds of homogeneity tests: "absolute methods", applied to each series separately, and "relative methods", that require reference series for comparison. Often, in particular in case of historical series, only absolute methods can be applied, as no other contemporary series in neighbouring locations are available.

Besides statistical tests, graphical methods are also used to investigate the homogeneity of historical records. A popular tool for precipitation is the double-mass curve obtained by plotting the cumulative amounts of the series under study against the cumulative amounts of another one or a set of contemporary neighbouring series. A horizontal straight line indicates homogeneity.

The three-century series (1713-2018) of precipitation in Padua has been tested for homogeneity, using statistical and graphical methods. Four homogeneity tests were selected, namely: von Neumann (VN) (von Neumann 1941), Pettitt (1979), Standard Normal Homogeneity (SNH) (Alexandersson 1986) and Buishand (Buishand 1982) tests. As these methods are able to identify one single shift, they were applied to the annual values of the whole series as well as to portions of it. These have been created coupling portions of the series characterized by different observers and/or locations: these are the critical points where turning points may occur.

The results of the 4 mentioned tests were checked at a 5% significance level and the results are reported in Table ESM.3 (the non-homogeneities are written in red). Under the null hypothesis, the annual data are independent and randomly distributed except for von Neumann test. Under the alternative hypothesis, Pettitt, SNH and Buishand tests assume that there is a year (indicated in brakets) at which a change in the mean of data series has occurred. On the contrary, VN test does not give any information on turning points.

Table ESM3. Results of the Homogeneity Tests

Period	VN		Pettitt		SNH		Buishand	
	N	p-value	KN	p-value	To	p-value	Q	p-value
1725-1811	1.515	0.012	476	0.279	5.437	0.275	9.165	0.212
1768-1838	1.234	0.0001	726 (1810)	<0.0001	19.219 (1812)	<0.0001	17.965 (1810)	<0.0001
1812-1864	2.061	0.589	331 (1843)	0.023	9.837 (1843)	0.021	11.206 (1843)	0.007
1839-1919	2.078	0.638	299	0.846	4.192	0.489	6.371	0.598
1865-1978	1.981	0.456	417	0.419	1.91	0.942	6.129	0.833
1920-2018	1.887	0.286	403	0.877	5.945	0.237	9.064	0.288
1725-2018	1.767	0.0244	3164	0.286	7.163	0.187	20.533	0.089

According to the results, the whole series resulted homogeneous, except for the VN test. Concerning the different portions of the series, two turning points were identified by almost all the tests, i.e., 1810-1812 and 1843. The first turning point, i.e. 1810-1812, occurred when Chiminello had the apoplectic fits (in 1809 and 1811) and Bertirossi-Busata took responsibility for the observations; therefore, the turning point can be ascribed to the change of observer and measuring

protocol. The second turning point, i.e. 1843, was at the beginning of the Santini period when the dome of the Meridian Circle Room was used as rain collector (1838-1877).

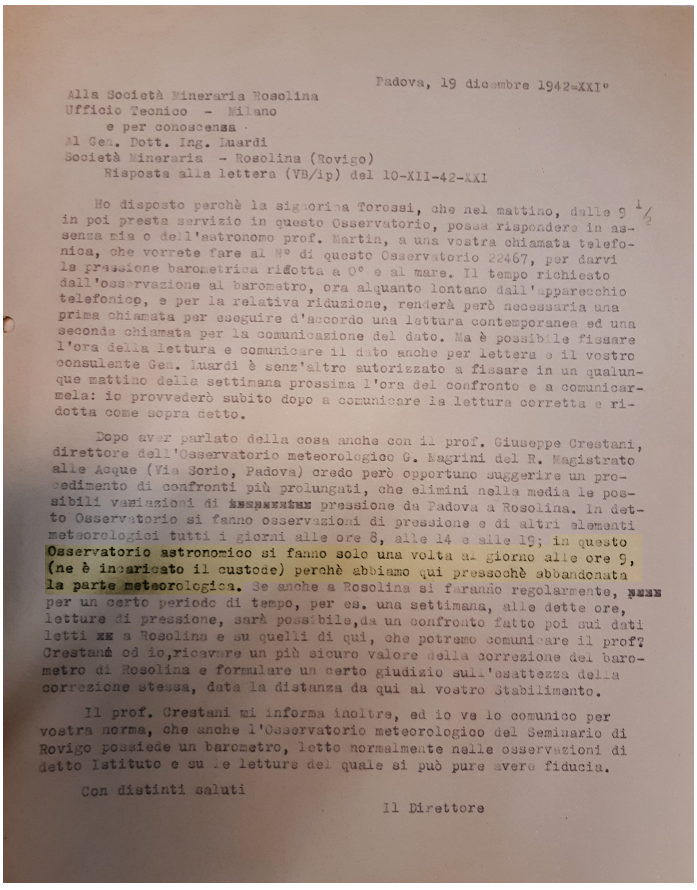
Il Direttore

Fig.ESM17e Letter dated 20 June 1942, confirming that meteorological observations were dismissed at the Specola.
Second paragraph: "In this Institute, *since some time, the meteorological observations are taken for internal use only*. For the next time, *for any meteorological issue, you are kindly requested to contact the local Meteorological Observatory* (i.e. the Magrini) of the Hydrographic Office of the Water Magistrate (56, Sorio street)" Signed: the Director



Padova, 19 dicembre 1942-XXI°

Alla Società Mineraria Rosolina
Ufficio Tecnico - Milano
e per conoscenza
Al Gen. Dott. Ing. Luardi
Società Mineraria - Rosolina (Rovigo)
Risposta alla lettera (VB/ip) del 10-XII-42-XXI

Ho disposto perchè la signorina Torossi, che nel mattino, dalle 9 ½ in poi presta servizio in questo Osservatorio, possa rispondere in assenza mia o dell'astronomo prof. Martin, a una vostra chiamata telefonica, che vorrete fare al N° di questo Osservatorio 22467, per darvi la pressione barometrica ridotta a 0° e al mare. Il tempo richiesto dall'osservazione al barometro, ora alquanto lontano dall'apparecchio telefonico, e per la relativa riduzione, renderà però necessaria una prima chiamata per eseguire d'accordo una lettura contemporanea ed una seconda chiamata per la comunicazione del dato. Ma è possibile fissare l'ora della lettura e comunicare il dato anche per lettera e il vostro consulente Gen. Luardi è senz'altro autorizzato a fissare in un qualunque mattino della settimana prossima l'ora del confronto e a comunicarmela: io provvederò subito dopo a comunicare la lettura corretta e ridotta come sopra detto.

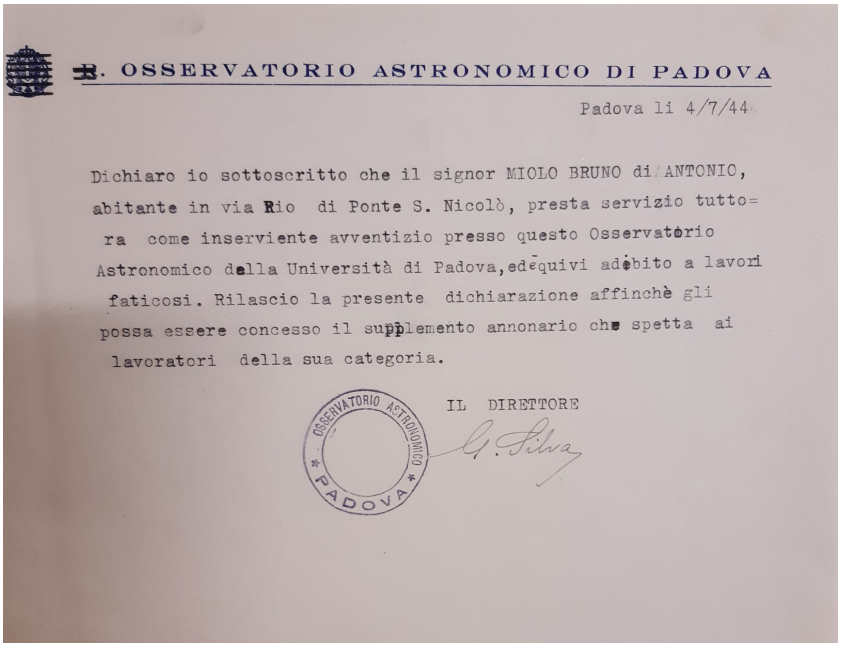
Dopo aver parlato della cosa anche con il prof. Giuseppe Crestani, direttore dell'Osservatorio meteorologico G. Magrini del R. Magistrato alle Acque (Via Sorio, Padova) credo però opportuno suggerire un procedimento di confronti più prolungati, che elimini nella media le possibili variazioni di pressione da Padova a Rosolina. In detto Osservatorio si fanno osservazioni di pressione e di altri elementi meteorologici tutti i giorni alle ore 8, alle 14 e alle 19; in questo Osservatorio astronomico si fanno solo una volta al giorno alle ore 9, (ne è incaricato il custode) perchè abbiamo qui pressochè abbandonata la parte meteorologica. Se anche a Rosolina si faranno regolarmente, per un certo periodo di tempo, per es. una settimana, alle dette ore, letture di pressione, sarà possibile,da un confronto fatto poi sui dati letti a Rosolina e su quelli di qui, che potremo comunicare il prof. Crestani od io,ricavare un più sicuro valore della correzione del barometro di Rosolina e formulare un certo giudizio sull'esattezza della correzione stessa, data la distanza da qui al vostro Stabilimento.

Il prof. Crestani mi informa inoltre, ed io ve lo comunico per vostra norma, che anche l'Osservatorio meteorologico del Seminario di Rovigo possiede un barometro, letto normalmente nelle osservazioni di detto Istituto e su le letture del quale si può pure avere fiducia.

Con distinti saluti

Il Direttore

Fig.ESM17f Letter dated 19 December 1942, confirming that meteorological observations were stopped long ago, and the limited skill of the observer.
Highlighted paragraph: "In this Astronomical Observatory, weather readings are made only once a day, at 9 a.m. (the *charged person is the building custodian)* because *we have almost already stopped the meteorological observations*".
Signed: the Director.



R. OSSERVATORIO ASTRONOMICO DI PADOVA

Padova li 4/7/44

Dichiaro io sottoscritto che il signor MIOLO BRUNO di ANTONIO, abitante in via Rio di Ponte S. Nicolò, presta servizio tutto= ra come inserviente avventizio presso questo Osservatorio Astronomico della Università di Padova, ed equivi adibito a lavori faticosi. Rilascio la presente dichiarazione affinchè gli possa essere concesso il supplemento annonario che spetta ai lavoratori della sua categoria.

IL DIRETTORE

OSSERVATORIO ASTRONOMICO * PADOVA *

Fig.ESM17g Letter dated 11 April 1944, defining the limited skill of Mr Bruno Miolo who noted weather readings on notepads.

"Myself I declare that Mr Bruno Miolo... is serving this Astronomical Observatory of the University of Padua, *assigned to fatiguing jobs*"
Signed: the Director G. Silva.

ESM 13. Raingauge in the last period of the Magrini Observatory

Fig.ESM18 In the last period of the Magrini Observatory, when it was left unmanned except for periodic change of the strip-chart recorder, only the tipping bucket raingauge in the garden was operated, and the others were removed. The Stevenson screen for the temperature and humidity readings is visible in bad conditions, and broken roof.

ESM 14. Supplement to Section 3: How observing time may affect readings

A long series is generally composed of a number of records taken over time by different observers and/or institutions. Every observation protocol establishes a certain time to read the amount of water collected into the raingauge or expresses the daily amount starting from a selected time, e.g. 0 a.m., 9 a.m, and so forth. Some kinds of precipitation may occur at any time, e.g. the passage of a front, others may be caused by specific phenomena related to the daily solar cycle, e.g. sea or mountain breeze, showers generated by thermo-convective activity. The former is randomly distributed over the day, the latter follows a daily and a seasonal cycle, and the choice of the start of the collecting time might be suspected to be influential on the determination of the precipitation frequency and amount at daily, monthly or yearly level, with departures inversely related to the selected time duration used in the statistical representation.

A test has been performed with the hourly precipitation data collected by the of "Padua Legnaro" station (ARPAV), located 10 km south of the Padua city centre, from 2009 to 2018. In the figures reported below, the precipitation frequency is plotted versus the hour of the day at yearly and monthly levels, with the monthly analysis divided in seasons.

In the yearly precipitation, **Fig.ESM19**, a distinction has been made between classes of precipitation amounts, in order to point out the influence of a threshold, i.e. precipitation larger than 1 mm, 5 mm and 10 mm. The distribution is uneven and especially the precipitation > 1 mm shows a daily swing with a minimum precipitation frequency in the morning, and a maximum in the late evening and early night.

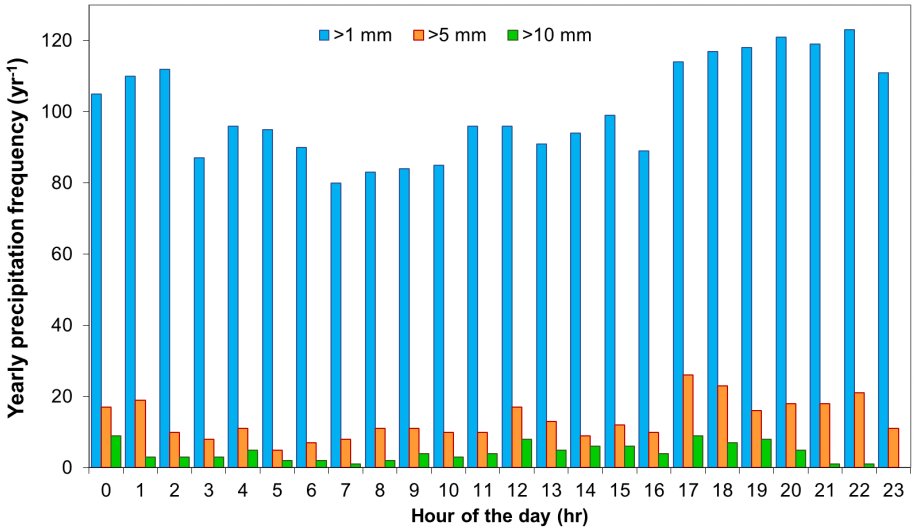


Fig.ESM19 Yearly frequency of different classes of precipitation amounts (i.e. >1 mm, >5 mm and >10 mm) found over the daytime

The monthly distributions **Fig.ESM20a,b,c,d** show that each month has its specific character. In particular, the summer months are characterized by a marked minimum in the morning and a maximum in the afternoon and the evening, related to the ground heating, the development of thermo-convective activity and the formation of cumulus clouds. As opposed, in winter the daily cycle is less evident.

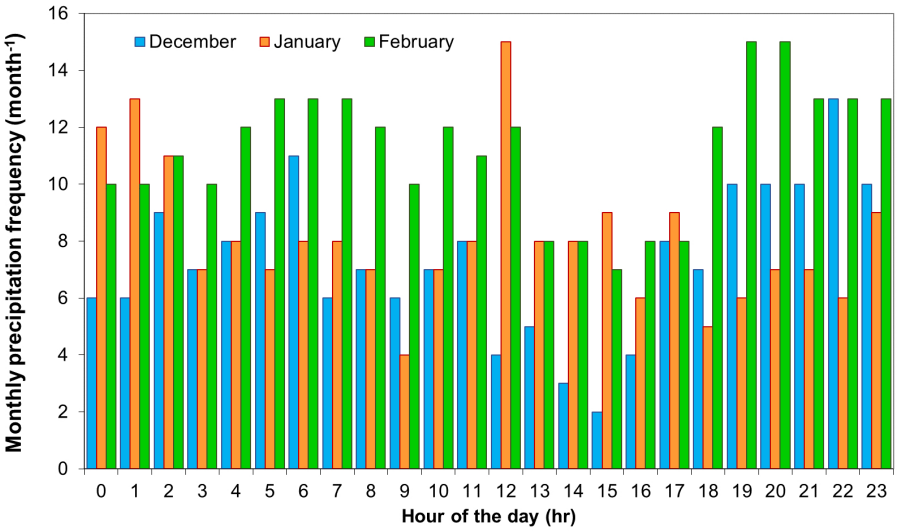

Fig.ESM20a Monthly distribution of the precipitation frequency over the daytime in winter

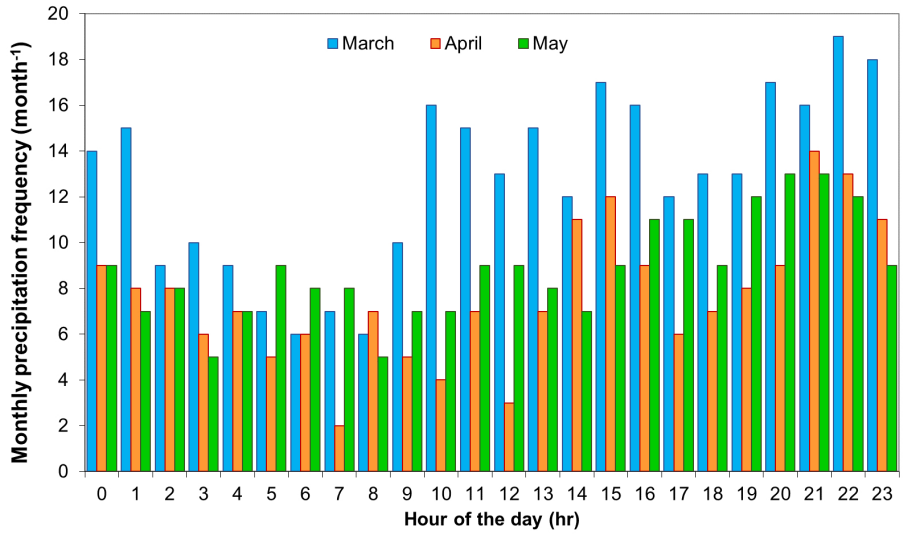

Fig.ESM20b Monthly distribution of the precipitation frequency over the daytime in spring

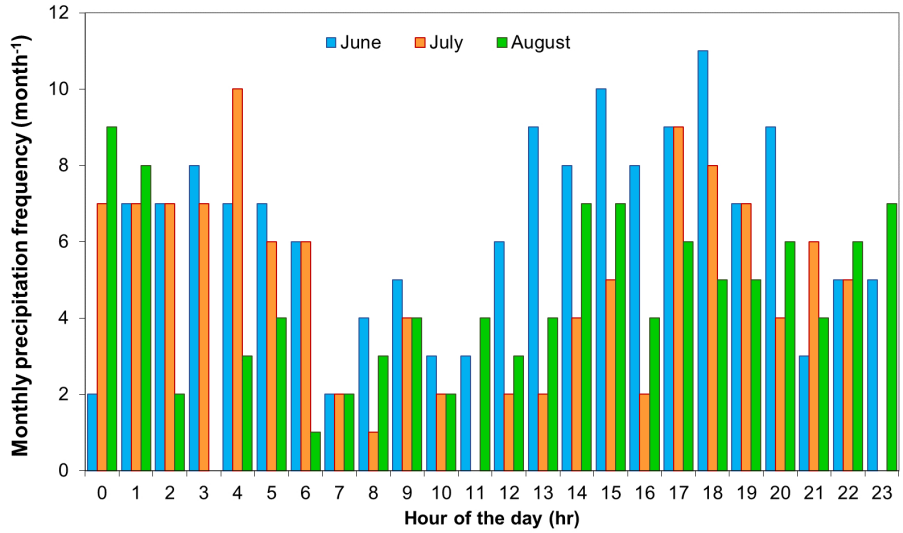

Fig.ESM20c Monthly distribution of the precipitation frequency over the daytime in summer

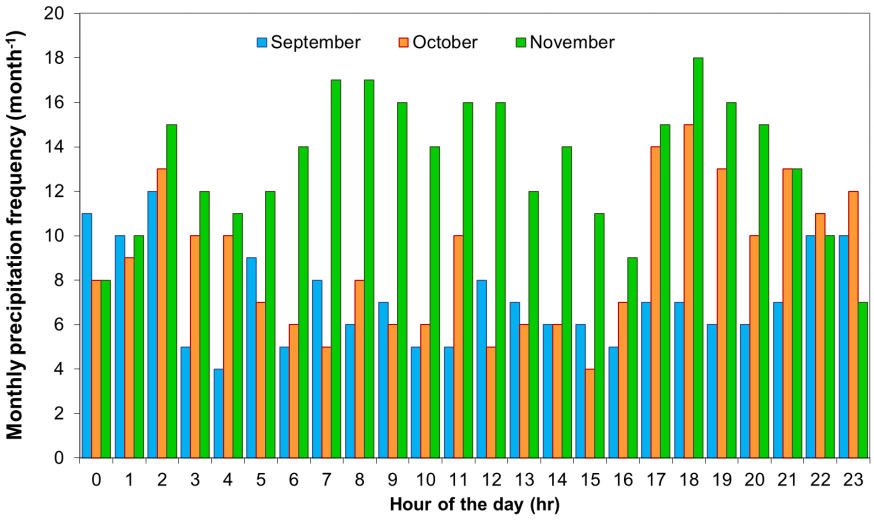

Fig.ESM20d Monthly distribution of the precipitation frequency over the daytime in autumn

The above statistical representations have shown that some months are characterized by a random distribution over the day, others by daily cycles, and the question is how influential this fact may be if the observer changes the scheduled time for reading the precipitation collected by the raingauge.

Tests made on the record give small, randomly distributed fluctuations. This can be easily explained. Suppose that the precipitation in a certain region can be represented as a sum of a random and a cyclic distribution. By the definition of a random component, the average of the values met over the next 24 hours is independent of the starting time. By the definition of a cyclic component, with 24 hr period, the average of the values met over the next 24 hours is independent of the starting time. In conclusion, if the scheduled reading time is shifted, every day will lose something of the previous day, but it will also gain something from the next one. For a cyclic component the difference is null, for a randomly distributed component the difference is a small, fluctuating value. In the case of monthly precipitation, part of the information of the first, or the last day of the month may be shifted from/to the previous/next month. In the case of yearly values, only the first/last day of the year may undergo a partial exchange with the previous/next year.

In conclusion, the change of the scheduled time for reading the raingauge does not introduce systematic or relevant errors in the series.

On the other hand, it may happen that a peak occurs around the sampling time and is partitioned between two consecutive days. This exceptional combination may transform an exceptional precipitation into two normal rain days. However, this event is absolutely unpredictable, and irrespective of any choice of scheduled time. Contemporary daily records, taken at different observing times, may have different peak values, but almost the same monthly amount.

ESM 15. Supplement to Section 3: Differences between contemporary stations and between Fig.7d of this work and Fig.1 in Marani and Zanetti (2015)

This investigation has been requested by Reviewer#1, Marco Marani, who sent us his dataset updated to 2018. He asked a comparison with our data to investigate if there are differences between the two datasets, especially for the 20th century when more than one station was active and operated simultaneously. The comparison between different stations should put into evidence their relationship, while the comparison between two datasets from the same source should point out any misprint. The use of different stations should explain the main differences between Fig1 of Marani and Zanetti (2015) (hereafter referred to as M&Z) and Fig.7d of this work.

From 1725 to March 1764 the source of data used by M&Z and this work is the same (Poleni), and the related parts of Fig1 M&Z and Fig.7d of this work are identical.

From April 1764 to December 1768 measurements are missing. Therefore, in this work a gap has been left, while in M&Z the gap is filled. However, the source has not been declared.

From 1769 to 1919 the source of M&Z and this work is the same, i.e. the Specola. However, especially from 1812 to 1861, readings are not always regular as explained in the text. Moreover, some days have additional readings, taken at different or shifted times, or reporting the precipitation during the night. In some cases, the choice between two consecutive days (i.e. to make shorter the first day and longer the second one or vice-versa) is not easy and this may increase/decrease the amount of a specific day, but it leaves unchanged the sum of the two days. This is irrelevant when dealing with monthly totals, but might be relevant when daily amounts are separately considered, or when extreme events are analysed.

After 1920, M&Z declared of having relied on: Specola till 1934; Magrini Observatory of the Water Magistrate 1935-1996; ARPAV Botanical Garden 1997-2006. The first two stations were not in their best period. As explained before, the Director of the Specola, Giovanni Silva officially stopped the logs in September 1938 (Fig.ESM17a) as well as any other meteorological activity, except for internal use (Fig.ESM17e,f,g). The Magrini Observatory carried out an excellent activity of service and research under the direction of Augusto Levi in 1920 and Giuseppe Crestani from 1921 to 1958. However, in 1973 a special law reformed the public services concerning the safeguarding of Venice and its hinterland, and the Water Magistrate lost its leading role. The staff was reduced or passed to other public administrations; the Magrini Observatory was downgraded to a station with unattended recording instruments (Fig.ESM18) and periodic collection of the strip records. The Water Magistrate was ultimately suppressed in 2014 and its competences were transferred to ARPAV. We had direct contacts with the staff that operated with Crestani and we could inspect the site and the instruments since the 1970s, witnessing the deteriorating situation. After Crestani, the data quality worsened and some gaps were originated. M&Z used records taken in the worsening period and filled the missing data with the Legnaro station that is 10 km far from the Specola. The last station, i.e. ARPAV Botanical Garden, was born as University of Padua, had some difficulties at the beginning, then passed to ARPAV and became of excellent quality.

On the ground of the historical research, this paper used the following records. 1920-1950: Magrini Observatory, that was in its best period; 1951-1990: Meteorological Service of the Italian Air Force; 1991-2018: ARPAV Botanical Garden.

The first test (Fig.ESM21a,b) is aimed to highlight the differences between the precipitation frequency and amount recorded at the Specola (used by M&Z) and the Magrini Observatory (used in this work) over the period 1920-1934. Marani asked to a comparison between the daily data but this analysis was not much representative because the Specola made readings at 9 a.m. and Magrini at 0 a.m (Fig.ESM17f) and the two readings will likely differ in both frequency and amount. To reduce this drawback, the monthly totals were considered. The comparison has been made plotting the monthly totals of one station versus the monthly totals of the other.

In 1920-1934, the frequency (Fig.ESM21a) shows a large scatter, i.e. $R^2 = 0.64$. Dots falling on the bisector (blue line) indicate that both stations gave identical readings. However, the dataset is shifted upwards and the slope of the best-fit line (1.09) indicates that the frequency measured at Specola is less than Magrini Observatory. The two stations are at short distance (i.e. 750 m) and should have very similar readings, at least in average. However, a number of reasons may justify this result, i.e. the observation days started at different times, i.e. 9 hr difference; the raingauges were exposed at different levels above ground; the Specola had a higher instrumental threshold or the frequency was underestimated for less regular observations.

The precipitation amount (Fig.ESM21b) is less scattered, i.e. $R^2 = 0.87$. The slope of the best-fit line 1.18 indicates that the Specola dataset has lower values than the Magrini Observatory. As the two averages are 59.9 and 72.6 mm/month respectively, the Specola collected 79% of the water at the Magrini Observatory. It might be useful to remind that, if $R^2 \neq 0$, the slope of the best-fit

straight line does not coincide with the tangent created with the two average values, i.e. their ratio 72.6/59.9 = 1.21, because the best-fit slope is built with the least square method (i.e. minimizing the squared distance of each point from the best-fit line) that implies use of non-linear operators, while the average is based exclusively on linear operators.

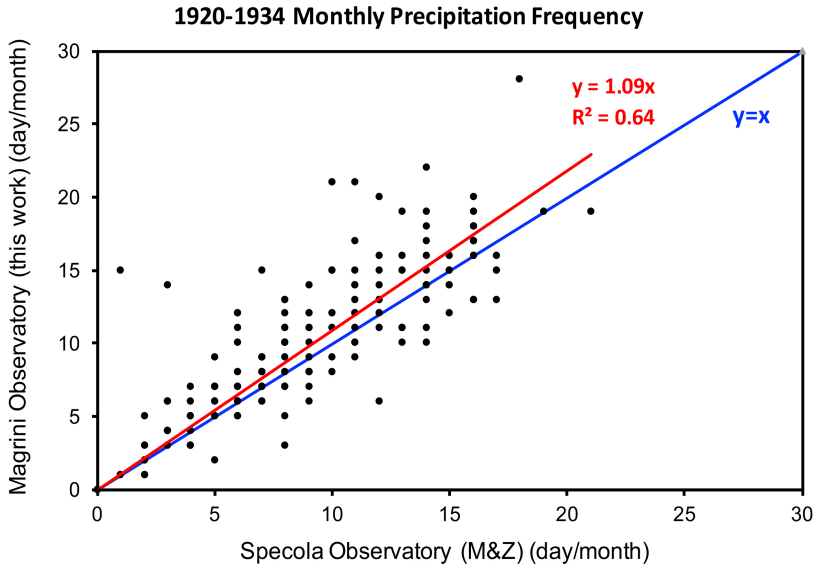

Fig.ESM21a Monthly precipitation frequency measured at the Specola versus the Magrini Observatory of the Water Magistrate from 1920 to 1934. Blue line: bisector; red line: best-fit.

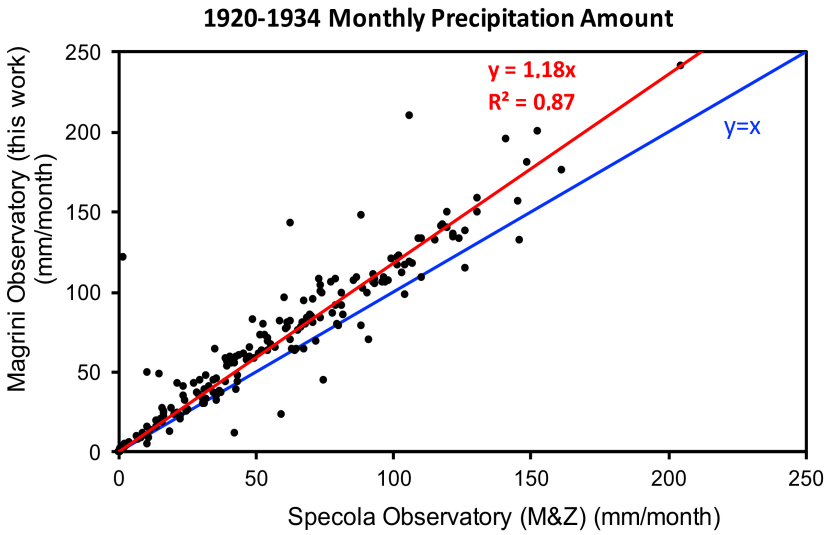

Fig.ESM21b As in (a), but for monthly precipitation amount.

The second test concerns the next period, i.e. 1935-1949, in which both M&Z and this work used the same source, i.e. the Magrini Observatory (Fig.ESM22a,b). Reporting the dataset used in this work versus the one of M&Z, one should expect to obtain only data falling on the bisector (maybe except some misprints that will be highlighted) and R^2=1. Surprisingly, the situation is different.

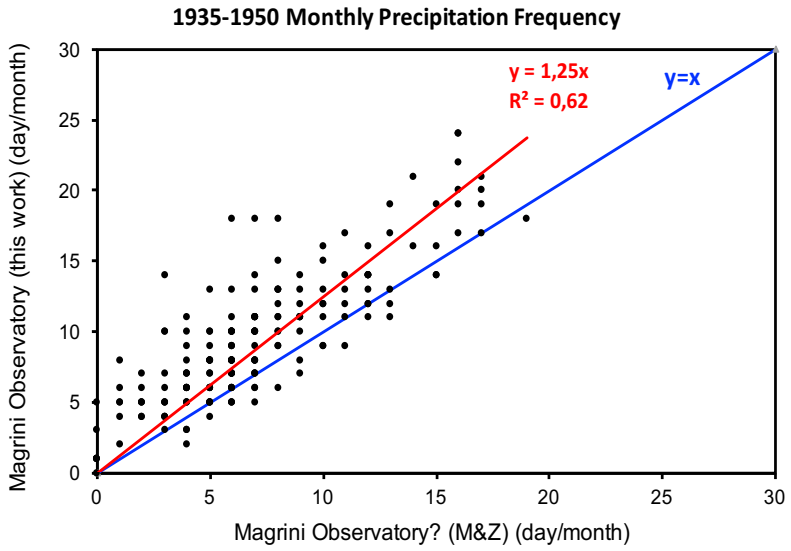

Fig.ESM22a Monthly precipitation frequency from the 1935-1950 dataset used by M&Z (declared to be the Magrini Observatory) and the true dataset of the Magrini Observatory used in this work. The plot shows that M&Z used a different source. Blue line: bisector; red line: best-fit

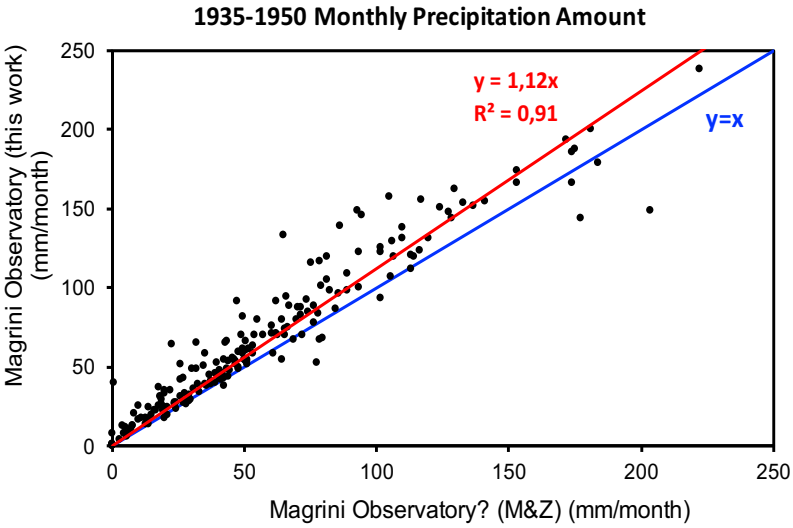

Fig.ESM22b As in (a), but for monthly precipitation amount.

Both frequency and amount show that the datasets are different between them. In particular, the frequency data shows a large scatter (i.e. $R^2 = 0.62$) and the best-fit with slope 1.25 shows that the dataset used by M&Z under-evaluates the frequency respect to the source used in this work. This difference is very high and might suggest some observational bias (e.g. higher instrumental threshold, two consecutive rainy days considered as only one) or that another station was used. The amount shows less scatter, i.e. $R^2 = 0.91$, with best-fit slope 1.12.

The above plots suggest that the two datasets arise from two different sources, although correlated between them. The cross-control shown that our dataset does correspond exactly to the source, i.e. the Magrini Observatory, but not the M&Z dataset, although the Authors declared that for this period they relied on the Magrini Observatory.

A comparison with the documents in the Historical Archive of the Astronomical Observatory has recognized that the data of M&Z are identical to those reported in the last non-validated period of the Specola, ended in 1950. As explained in the text, the Specola ceased all interest for meteorology in 1938 and the Director Silva declared that readings were solely for internal use, i.e. not the best choice to reconstruct a centuries-long series.

The reason why M&Z misrepresented the source may find an explanation in the acknowledgements, i.e. Marani did not personally oversee the data recovery, but was thesis advisor

of Andrea Dal Maso (2006) and Luca Rapacciuolo (2007) who recovered the data for their dissertation about the Padua precipitation series, statistical analysis and extreme events, held at the Padua University.

For 1997-2018, both M&Z and this work relied on the same station, i.e. ARPAV Botanical Garden. In the plot, this is evident because the best-fit is close to the bisector, with a few scattered data (Fig.ESM23ab). Scattered data might be explained with misprints, non-validated data, or gaps filled with different stations. The non-validated data are uploaded in real time by ARPAV to provide a public service, especially in the case of weather or pollution alert. Later, the informal data are substituted with the validated data. In our case, we should exclude misprint in copying or using non-validated data because ARPAV kindly supplied us the file with the validated record.

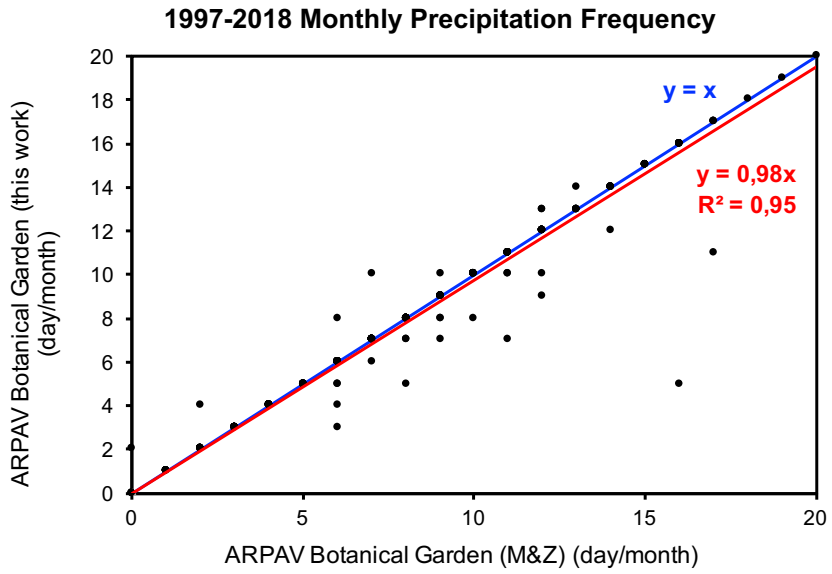

Fig.ESM23a Monthly precipitation frequency from the 1997-2018 dataset of ARPAV Botanical Garden. Blue line: bisector; red line: best-fit.

ESM 16. Comparison between the Specola and the Magrini Observatory

The Specola and Magrini Observatory are at short distance between them (i.e. 750 m) and operated simultaneously for 31 years. One might expect to find the same average readings, except for:

- the difference of the height of the funnels above ground (i.e. the Specola raingauge was exposed on the roof, at 20.7 m above ground, and the Magrini at 1.2 m);
- the difference of the hour selected for the raingauge reading (i.e. 9 a.m. for the Specola and 0 a.m. for Magrini). However, this is minimized over the long-term integration period;
- some possible unknown biases (e.g. the Specola might have had a higher instrumental threshold or the frequency was underestimated for less regular observations).

Over a 31-year period, the bias for the different reading times vanishes as well as other random errors. If potential biases may be considered negligible, this gives the opportunity to evaluate the relationship between two raingauges collecting rain at two different levels, i.e. 1.2 and 20.7 m (Fig.ESM24a,b)

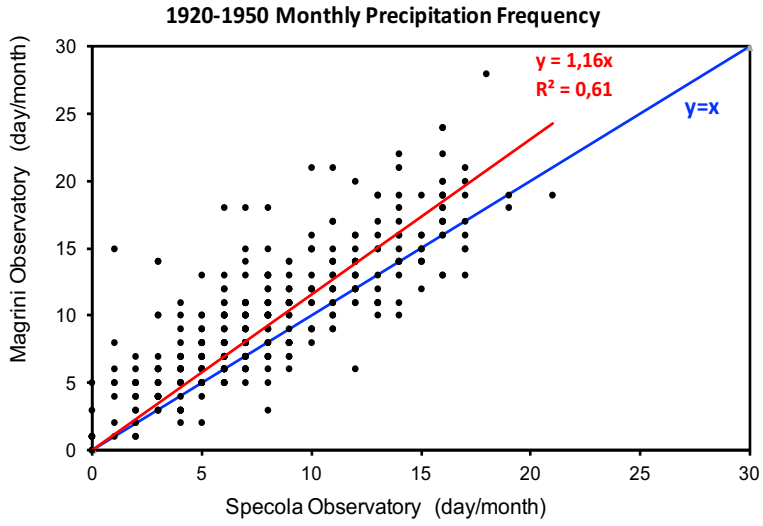

Fig.ESM24a Monthly precipitation frequency measured at the Specola and Magrini Observatory from 1920 to 1950. Blue line: bisector; red line: best-fit.

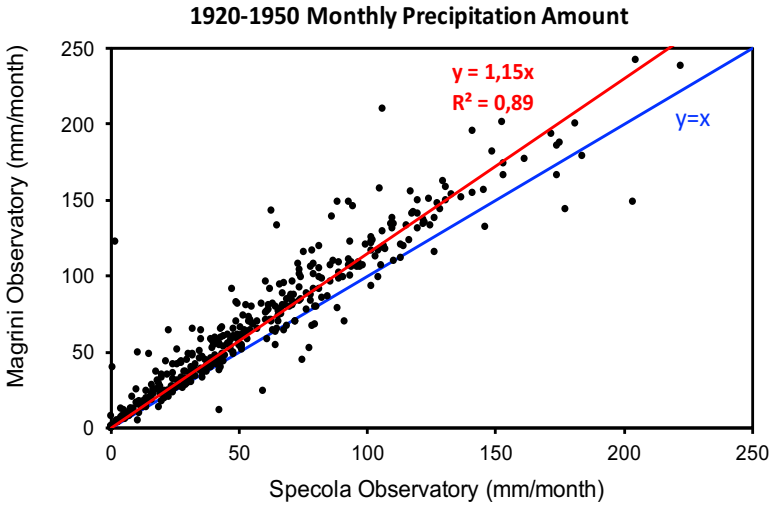

Fig.ESM24b As in (a), but for monthly precipitation amount.

The slope of the best-fit of the frequency is 1.16; the average frequency at Specola 8.1 day/month and at Magrini 9.9 day/month, i.e. the frequency recorded at the Specola is 81% of Magrini, i.e. 19% less. The slope of the best-fit of the amount is 1.15; the average amount at Specola 59.5 mm/month and at Magrini 71.1 mm/month, i.e. the amount recorded at the Specola is 84% of Magrini, i.e. 16% less.

The two slopes of the monthly frequency and monthly amounts at the Specola and Magrini Observatory, as well as the related percentages of the Specola to the Magrini Observatory ratio are similar between them, and both confirm that the Specola underestimated readings.

The found underestimation percentages that have been found are bigger, but consistent with the results of some case studies where funnels located 20 m above the ground had a reduction of the order of 10% in comparison with a reference raingauge at ground level (Camuffo 2019).

ESM 17 Consulting data of the Magrini Observatory of the Water Magistrate

It may be useful to explain that the archive data of the Water Magistrate, including the Magrini Observatory, can be consulted on the website of ISPRA (*Istituto Superiore per la Protezione e la Ricerca Ambientale,* i.e. Superior Institute for Environmental Protection and Research):
http://www.acq.isprambiente.it/annalipdf/

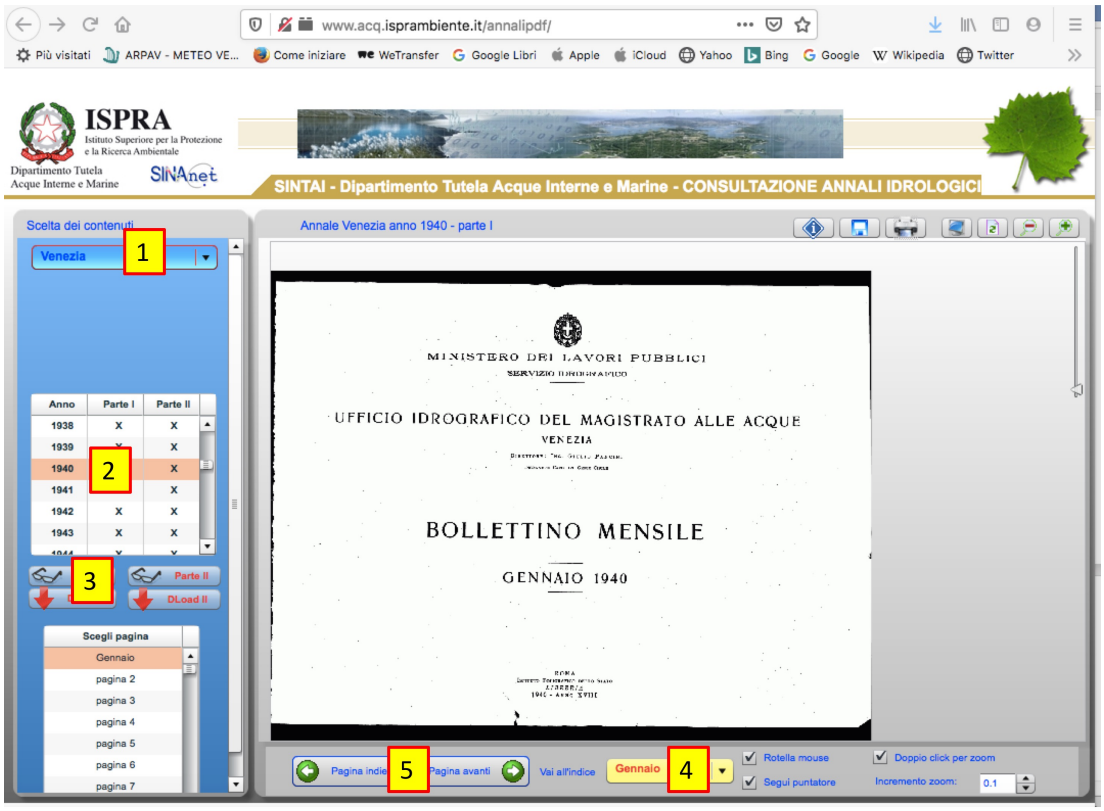

Fig.ESM25. Screenshot of the ISPRA Webpage to get the record with numbers on the yellow squares indicating the procedure.
(1) Select and click "*compartimento"*: Venezia (yellow square 1)
(2) select the year "*Anno"* (yellow square 2)
(3) select *Parte 1* (yellow square 3). The red arrow in the lower line (3) is to download the whole yearly bulletin.
(4) select the month "*vai all'indice"* (yellow square 4)
(5) scroll pages until the required page is found. The Magrini Observatory is indicated as: "*Osservatorio di Padova (via Sorio)*, North Latitude 45° 24', Longitude 0° 35' West of Rome" (yellow square 5)

Acknowledgements
The authors are grateful to: Dr Riccardo Guolo and Dr Francesco Rech, ARPAV, Teolo Meteorological Service, for having kindly supplied and permitted to publish the precipitation data of ARPAV and Water Magistrate; © The Historical Archive of the Astronomical Observatory, Padua; © The Marciana Library, Venice, for having kindly allowed the consultation and permission to publish the documents; Elsevier, The Science of the Total Environment for having permitted to reproduce the Fig.2 of Camuffo et al. 1984, 1988.

ESM 18. Raw Data Cover Concerning the Daily Precipitation in Padua

In the next pages, the datasets with original records are reported. They are property of the following Institutions:

- **INAF Astronomical Observatory** www.beniculturali.inaf.it/archivi/padova/#serie (pay attention to some biased periods as explained in the text)
- **Magrini Observatory of the Water Magistrate** after the **ISPRA** (*Istituto Superiore per la Protezione e la Ricerca Ambientale*, i.e. Superior Institute for Environmental Protection and Research) website http://www.acq.isprambiente.it/annalipdf/ Note: the Water Magistrate was closed in 2014 and its competency was transferred to ARPAV
- **ARPAV** (*Agenzia Regionale per la Prevenzione e Protezione Ambientale del Veneto*, i.e. Regional Agency for Environmental Prevention and Protection of the Veneto Region), website https://www.arpa.veneto.it/
- The data recovery and analysis constitutes intellectual property of the **Authors**

In this work, a dataset has been used of the **Weather Service** of the **Italian Air Force**, official website http://www.meteoam.it/dati_in_tempo_reale
However, we are not authorized to report here their data because "*All Users are obliged not to transfer to third parties the original data or products released by the Weather Service*". Interested people should directly contact the Weather Service.

The **Authors of this paper** have recovered the data from the original handwritten documents, or printed tabular forms, and transformed the data from their units (e.g. London inch for Poleni, Paris Inch for Toaldo etc.) into mm, and at the end of a long historical research they have associated the data to their metadata; in particular, when the data are uncertain, or affected by bias or other problems.
